It might, but that would not be the best way to tackle that problem. If he has common mode problems he would be better off using a better balun or choke. If he ran a 12v solid state rig from an AC power supply, the power supply is the only thing that "really" needs to be grounded. And most power supplies usually safety ground using a third ground pin on the power cord. But this assumes the grounded pin on the socket is actually properly grounded. If the radio is run off a battery, no ground is really needed at all. I would consider it optional. MK

There is no added complexity, Richard, which tells me that you may
be ignorant of the details. See below.

>>anything going on here).

Wave cancellation requires an impedance discontinuity, Richard. Your
two slit example is an irrelevant diversion. Here is an example of
wave cancellation: Two coherent waves traveling in the same direction
have been created at an impedance discontinuity. They are reflected
energy waves 1 and 2:

Wave1: 100V at 0 degrees with 2A at 180 degrees

Wave2: 100V at 180 degrees with 2A at 0 degrees

What happens when you add those two waves?

4669. Coaxial Dipole Design

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-13 21:30:53 UTC
From: Chris Bronson <lordmastema@hotmail.com>
Message-ID: <3dfa51cb_2@news.bluewin.ch>
Source record: 129208

Hi,

I recently encountered a VHF coaxial dipole manufactured by Wipic in the 70s. The radiating element is grounded at its upper extremity by the inner tube of the antenna. What are the theoretical and practical advantages of such a design vs. a conventional coaxial dipole? Thanking you in advance for your help. Regards

Chris

Please find a technical drawing of the antenna on:
http://chrisbronson.freeservers.com/Wipic_Coaxial_Dipole.gif

Mark Keith wrote:
"It might (rig ground mitigate r-f in the shack), but that would not be the best way to tackle the problem."

Oh yeah?

A perfect ground and a 3/4-wave line would present a very high impedance at the dipole with no balun involved. I said may, not will mitigate r-f in the shack. Andy may have no balun and may not be disposed to install a balun.

What`s best, depends on the user.

Best regards, Richard Harrison, KB5WZI

Hi Cecil,

With no surrogate either offered by you, or having stepped up in
several hours to offer an explanation that conforms to your
understanding - a closing synopsis:

We began with several premises:
>>>We don't have to worry about that in transmission lines.
So that we are on the same page, all waves are CONFINED to a
transmission line.
>>>that's all there is, two and only two waves
Ditto on being on the same page. TWO waves are CONFINED to the same
transmission line.
>>>they are from the one and only source in the system and are coherent.
Ditto on being on the same page. TWO waves are CONFINED to the same
transmission line driven by ONE SOURCE and they are COHERENT (even if
one is inverted with respect to the other).

That is sufficiently simple to not warrant a call on Occam's Razor
(barring someone's dispute). Then we enter into a nebulous region:

>>>they both encounter an impedance discontinuity
which is fine, but how did we get the two waves, from a single source,
BEFORE this discontinuity? Either something has not been revealed, or
this statement is in error.

This drives more complexity into the discussion with the odd notion
that:
>>>Being "sensible" to each other is what allows destructive interference
>>>between components of two different coherent waves traveling in the same
>>>direction.
Components? This dilutes the original TWO wave understanding (and
does not respond to where the second of the two came from, a problem
that is beginning to compound into even more complex explanations).
However, that is trivial in comparison to the basic mis-application
found in this quote above that denies the same operation of
interference in BOTH directions which is a fundamental property of TWO
COHERENT waves in a CONFINED line irrespective of all other
embellishments offered or to be added in the future.

The problems of this logic you offer is now doubly compounded and we
suddenly find a novel proposal for a "Particular" style of
interference that requires yet more explanation:

On Thu, 12 Dec 2002 22:17:09 -0600, OC_CAM's Razor
<Cecil.A.Moore@ieee.org> wrote:

> waves that emerge ... identical to the way they were before
> waves that don't emerge at all
>Hint: One set of waves doesn't get canceled and one set does.
makes no sense at all. The statement violates the conservation of
energy (where did the canceled energy go?). This compounds error to
the third degree. You have less energy at the end than you do at the
beginning and you till haven't explained where the balance is. You
haven't explained how two waves that exist in a closed system with
only one source; that are coherent (allowing for one wave's inversion
where appropriate); and that DO combine destructively in only one
direction and that DO NOT combine at all in the other (not even
constructively!) can exist as a physical reality. There is nothing in
physics that supports this odd relationship.

My stripped down discussion of classic interference:
>
>If I see the projection of the sun through a double slit against a
>screen, I will see light and dark bars due to "interference." There
>is absolutely nothing here that requires an impedance discontinuity.
>There is no causal effect enforced on either of the two slits, one on
>the other (they remain independent sources). The two waves are wholly
>independent of each other before they fall on the screen, and after
>they reflect (there is no magic zero time at the screen to change
>anything going on here).
was met by the steamroller and obvious indifference to the contrast
your argument makes with classical physics. This simple observational
evidence (Occam at his best) encompassed all the baggage of your
unnecessary embellishments and complexity of a crafted solution to
show they were false assertions across the board.

4673. WANT Active Dual SWR Power Meter or schematic

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-13 22:28:45 UTC
From: "frazier@flex.com" <frazier@flex.com>
Message-ID: <3DFA5F1D.69FA154F@flex.com>
Source record: 129212
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.antenna,alt.radio.amateur

I've got a SignalCrafter model 30 SWR Power meter and would like to find another in working condition, or another SWR/Power meter with similar features.

The SignalCrafter Model 30 has two meters. The lefthand one displays Power in three ranges, 20W, 200W, and 2000W. The righthand meter displays SWR, and under the SWR scale is something they called reflection coefficient. It also provides the ability to switch between three antennas and a dummy load. I don't care about the switching for antennas, as I only use mine for a SWR/Power meter, and use a different custom switching array for my antenna switches.

The SignalCrafter Model 30 was made in the early 80's and is an ACTIVE SWR meter. There is no "set" knob or need to mess around with anything other than the switches that select the power level. It's operation is very similar to the dual panel meters that are built into the JW Miller AT2500 Antenna Tuner of similar vintage.

Does anyone know of the availability of a SignalCrafter Model 30 or similar unit, or have a schematic that could be used to modify (add circuitry) to the existing cross needle swr meters in my MFJ Differential T Tuners? I really dislike the cross needle meters that require you to interpret the swr by reading a red line where the needles cross. I can pretty easily make a new dial scale if I can get a schematic to build the active circuitry to drive the meters.

Thanks
-- Rick AH7H

Richard Clark wrote:
> which is fine, but how did we get the two waves, from a single source,
> BEFORE this discontinuity? Either something has not been revealed, or
> this statement is in error.

You are mixing gasoline and water. The two separate topics are:

1. What happens to two and only two coherent waves traveling in same
direction in a transmission line. There's no impedance discontinuity
to worry about.

2. What happens when two coherent waves, traveling in opposite
directions, encounter the same lossless impedance discontinuity.

Pick one and let's discuss it. Then we can discuss the other.

> Components? This dilutes the original TWO wave understanding (and
> does not respond to where the second of the two came from, a problem
> that is beginning to compound into even more complex explanations).

Again, you are mixing two completely different topics. We can discuss
each separately but we cannot discuss both in the same breath.

> However, that is trivial in comparison to the basic mis-application
> found in this quote above that denies the same operation of
> interference in BOTH directions which is a fundamental property of TWO
> COHERENT waves in a CONFINED line irrespective of all other
> embellishments offered or to be added in the future.

I have NEVER denied interference in both directions. Waves traveling in
opposite directions don't cancel. Waves traveling in the same direction
can cancel. What is it about "don't cancel" Vs "can cancel" that you don't
understand?

> The statement violates the conservation of
> energy (where did the canceled energy go?).

You don't understand. When I say the wave is canceled, I mean that the
voltage and current goes to zero. But energy CANNOT be canceled. The
cancellation of two coherent waves traveling in the same direction in
a transmission line causes an energy reflection in the opposite
direction, i.e. destructive interference causes a reflected wave of
constructive interference in the opposite direction.

We have TWO separate topics? This is becoming more bizarre and
neither topic responds to the question quoted above. And this was the
trivial error.

Cecil, you have already admitted that this may be a failure of
your/our communications and as you have yet to offer a substitute for
yourself that is equally versed in your view - I am stepping out as
your layers of complexity are becoming absolutely Byzantine.

Write again, later, when you find a collaborator who understands you.

>...(every)...fifth person is
carrying a handgun out in the open.<

Should have made a distinction. While most citizens may openly transport a holstered sidearm on their person without a permit, only permitted person may carry a firearm concealed from view. However, if you "carry concealed", it had better stay hidden from view to those around you at all times, or you could get into a heap of deep hazoonga. In that regard, someone with a permit may have fewer rights than someone without.

Cellphone brandishers, on the other hand, may shamelessly conceal or flaunt their fractals anywhere---like tawdry farmyard animals! Disgusting.

What is the exect question ? Are you solving for a 1/2 or a 1/4 wavelength
of line ? You do not devide the length by 2 just because it is parellel
line. It would be the same for coax or parallel line except for the
velocity factor which is about .95 for parallel lines and from about .66 to
.8 depending on the type of coax.

Channel Master is apparently one of the few manufacturers still making this type antenna. They have a large antenna which covers channels 2,3 and maybe 4, I forget. I bought one for channel 2 for the same reason as you have. Find a dealer, and also purchase a channel 3 insertion filter, commonly available from satellite (C-Band, Big Ugly Dish) suppliers. It will notch out channel 3 from the main antenna and provides a connection to connect the channel 3 antenna.

Wonder what you're trying to calculate the physical length of.

300/f(MHz) X velocity factor = one wavelength of transmission line, in meters.

A quarter wavelength of transmission line, in meters, is 1/4 this value.
A half wavelength of transmission line, in meters, is 1/2 this value.

To calculate the inverse log (base 10) of X, raise 10 to the X power.
For example, the inverse log of 2 is 10^2 = 100. The log of 100 = 2.

visible or carried in luggage. Subsection A, paragraph 2 of this
section shall not apply to a weapon or weapons carried in a case,
holster, scabbard, pack or luggage which is carried within a means of
transportation or within a storage compartment, trunk or glove
compartment of a means of transportation.

Note that in AZ the law says that if your weapon is in a holster, you
can carry concealed in your car without a permit. Unfortunately, the
courts do not follow the law and have allowed the conviction of
persons who carry a holstered weapon in a vehicle. Another case of
the courts making law.

Similarly in CA the statutes say:

"12026.1. (a) Section 12025 shall not be construed to prohibit any
citizen of the United States over the age of 18 years who resides or
is temporarily within this state, and who is not within the excepted
classes prescribed by Section 12021 or 12021.1 of this code or Section
8100 or 8103 of the Welfare and Institutions Code, from transporting
or carrying any pistol, revolver, or other firearm capable of being
concealed upon the person, provided that the following applies to the
firearm:

(1) The firearm is within a motor vehicle and it is locked in the
vehicle's trunk or in a locked container in the vehicle other than the
utility or glove compartment."

The CA Attorney General says:

"California Penal Code section 12025 does not prevent a citizen of the United States over 18 years of age who is not within any of the classes excepted from firearm possession and who resides or is temporarily in California from transporting by motor vehicle any pistol, revolver, or other firearm capable of being concealed upon the person if the firearm is unloaded and in a locked container."

Note the difference. The statute doesn't say a damned thing about the weapon needing to be unloaded. The AG makes up some law and states that it does.

If you would only discuss the simple matched example at
http://www.qsl.net/w5dxp/fig2.gif
all of your questions would be answered.

According to Dr. Best, we get the two and only two waves AFTER the
discontinuity. Have you read Dr. Best's QEX article? Have you read
my web pages?

Is a handgun (no "weapons" please) loaded or unloaded if the clip is in the handle--but isn't fully engaged and there's no chambered round?

By the same token, if you're talking on a cellphone with the battery in place but not connected, are you loaded?

'K',
Dividing 300 by the frequency in Mhz gives you one
wave length in free space. Multiplying by the velocity
factor will give you a 'physical' length in meters for
one wave length of feed line. Divide that by two and
you have the physical length of a 1/2 wave feed line in
meters. If you want the length in feet instead of meters
use 492 instead of 300.
To find ERP of an antenna system, total the component's
gain/loss figures. The total is the gain/loss figure for
the system. Don't need a log function.
'Doc

> What`s best, depends on the user.

Well, maybe easiest, I don't know about best. I just can't in good conscience advocate using grounded or "tuned" coax lines to "hopefully" reduce RF in the shack. I know it doesn't work half the time unless everything is just right. I learned this the hard way running a KW+ amp, and a rig that was picky about rf in the shack. What if he tries another band? Many use parallel dipoles on one coax. Mine works 4 bands without using a tuner. A grounded 3/4 wave of coax for one certain band won't do me much good. He doesn't have to buy or make a fancy balun. Just wind a choke from his coax feedline. I think there are better baluns though than a choke, for all band use. With the proper balun, he won't need to ground the line or rig to reduce rf in the shack, and the length of the coax won't matter. The feedline won't radiate either. Nothing wrong with adding a ground if he wants one, but he should fix the real problem correctly first. And the real problem that usually causes "RF in the shack" is poor decoupling from the antenna to the feedline. IE: "common mode currents" Not a lack of ground. Either that or the antenna is in the same room... That way the problem won't be cropping up on him again when the ground dries out, or whatever. I went though that too...The bi-annual reoccurring rf problem that would come out of nowhere...
Nothing wrong with your method per say, for that exact scenario, but that scenerio won't match too many of the people that read that I bet. To me, advocating grounding schemes to cure the effects of improper antenna/feedline decoupling is like advocating bubble gum to stop leaky radiators. But to each his own I guess... This is just my opinion and I'm sure opinions on this vary. MK

I can see your point, but other conventional VHF coaxial dipoles also have the advantage of beeing self-supporting. I was just wondering, because Wipic manufactured quite a lot of other dipoles which are all more simple from an ingeneering point of view, including coaxial dipoles with a single rod, or a folded rod, as radiator and a sceleton "tube" as the coaxial sleeve. Regards

Chris

Mark Keith wrote:
"I just can`t in good conscience advocate using grounded or "tuned" coax lines to "hopefully" reduce RF in the shack."

Mark gave a good analysis of the problem of tuned lines. They are inconvenient for multiband use. The lengths required change with the band. The ground connection may not be good enough to clamp everything in the shack to a low r-f voltage.

Mark notes that a good balun can be a wideband device which minimizes r-f on a rig that isn`t particularly well grounded. Mark suggests winding a few turns from the coax to form a choke in the feedline as an easy way to deter r-f. This has the advantage that no special core material is required.

A grounded rig (for r-f) is probably not more susceptible to feedback. All commercial balanced antenna system rigs I`ve seen, never the less, had excellent r-f grounding on the rigs by design. No doubt some commercial installations use baluns. I`ve seen many installations, but never saw a balun in any.

The ionospheric D-region reflects VLF signals as does the earth's surface. These two reflectors make a spherical cavity with the first resonance at about 8 Hz. A very good antenna system and VLF spectrum analyzer will show a slight peak in the background noise at this frequency. There is nothing mysterious about the Schumann Resonance.

Hello:

Using N connectors on the coax that connects a Discone in my attic to an NRD 545 being used (also) as a scanner
between 30 MHz and its 2 GHz limit. Do receiving only.

Thinking of using one of those old fashioned DPDT knife (or were they called blade or jacknife switches?) type
switches inserted in series with the coax to switch the aerial to ground, and disconnect it, when not being used.

When in use, the aerial's output would, of course, be going thru the knife switch.

Was wondering if there would be much loss due to the "high" frequencies involved ?

What about a conventional wafer type switch at these frequencies (receive only) ?

Bob

In my cases, grounding of the rig had no bearing on whether it had RF floating on it or not. If you had a common mode problem, you would have RF floating, ground or not. I've had many cases where adding a ground wire to the system when I was having shack RF problems , made no difference at all. Sometimes it made it worse. I used FS meters to find where my hot spots were. I've had cases where other feedlines to other antennas piped in RF. A FS meter will spot that quickly.

>

I bet they were fairly frequency limited though, and used other methods. Also I bet the gear wasn't as subceptable to RF as some of the newer ham gear. In my case, it was my habit of using outboard mike amps inside my mike bases that usually got me. I usually didn't have the problem if I used the stock hand mike. Most icoms require a mike preamp that is outboard from the radio. Even my newest 706g requires one for my low Z dynamic that I use. But it requires about half as much gain as the 730 I ran. Icoms with custom mikes and common mode problems don't usually get along. I notice the 706 is prone also. Now, take my old TS-830...It's nearly bulletproof as far as RF floating around the shack. If it act's up, you know you have a big problem. Every single time I've had a problem with RF, it's always been due to antenna or feedline problems. Not a single time was it ever due to lack of a ground. Myself, I use no "RF" ground to the shack anymore. If I need an RF ground, it's under the antenna where it belongs. I might mention that none of this has any bearing at all on the grounding I use outside for lightning. Also, I might mention that common mode current problems and SWR have no real relation. You can have a perfect match and have RF in the shack o-plenty if you lack decent decoupling. Or you can have a bad mismatch and have little at all. Or anywhere in between. The antenna /feedline decoupling is the key to avoiding these type problems. As far as shack grounding, the only useful purpose I see in it, is to keep all the gear's chassis at the same potential. I get that just plugging everything together. My puter is hooked up to all this also. It's part of my radio these

days. MK

At 400 mhz and above I would assume that you will have about 2 db or more of
line loss. Also lets make an assumption that the switch is about 500 ohms
impedance. That puts a 10 to 1 swr bump in the line. You have to look at
it as the antenna is the signal source. That 'bump' could cause you to
loose an additional 3 to 6 db of signal . If your line losses are more ,
you could loose even more signal.

So long as you keep the switch contacts bright and clean, I can't imagine there being any signal loss your ears can hear.

The knife switch would probably have a bigger surface area for the contacts.

On the other hand, a switch designed for coax would probably offer better shielding if you're worried about picking up appliance noise.

Not sure why you want to disconnect your antenna. Since it is attic mounted, there's small chance lightning will hit it.

Lightning doesn't have to "hit" a random wire antenna to induce fairly large voltages. I assume that this is not a controversial statement.

>...the good people are the bad people when they get mad.<

A gross generalization of the worst sort. One reason Michigan's approach to concealed carry is better than many is that they require training and demonstrated proficiency as a condition of carry. Many states (including NH) do not require training or qualification. Not good.

In my view, the idea behind firearm education isn't to prevent people from carrying, but to ensure those who do know their responsibilities and understand the technology entrusted to them. We require it to drive a car or operate a ham radio, so why is it "anti-american" to require it of a gun owner??

Now, if we could only convince cellphone nutcakes to take a test so we could go to the theater or out to dinner without having to listening to those damn things playing silly tunes and watching people talk to themselves. On the bright side, the most geeky of hams among us need not worry about walking around the mall talking on 2 meters! Suddenly, they're cool amundo!

There aren't very many people around here with "concealed carry
permits," although there are a few paranoiacs who carry concealed
weapons, anyway. A few months ago there was a jerk who got mad
because someone cut him off in traffic, so he speeded up, ran the
other party off the road, stopped, and was waving a gun around when
the cops arrived. They disarmed him and he got to cool off in a nice,
little, high-tech jail cell. He was lucky. If he'd done the same thing in
San Francisco, the cops would have killed him as a matter of course.
I'm glad to know that the paranoid wrecks who carry guns in your part
of the world never get mad, and always keep themselves under control.
It must be very safe there. Don't expect a visit from me anytime soon,
though.

Question is: Did he have a concealed carry permit? If not, he's probably
the kind of person that causes some of us to carry concealed weapons.

If the unit's bandspread will allow it to tune there without
degradation, then I may be able to program it for you (need to check and
see if I have the right cable).

You -really- don't want to go chasing copies of Motorola RSS
without buying it. Their licensing agreement is positively Draconian (I
know... I had to sign it to get my stuff started!), and their legal
eagles can and will make an example of anyone who they think is
trafficking in pirated RSS.

Anyway... http://www.bluefeathertech.com/rf.html -- Let me know via
E-mail if you want me to try programming that beastie.

Shortwave broadcast stations? You may have high-power transmitters on every available band at the same time and a few hours later every transmitter has changed bands.

Most shortwave broadcasters use balanced antennas, balanced transmission lines and well grounded transmitters and associated equipment. Often there is no ground at the antenna at all.. No baluns either as the system is balanced. Transmitter outputs are balanced. You coulld probably fit a car inside the transmitter, but you couldn`t fit one of these transmitters in a car. It may be snug in the trailer of a 18-wheeler.

Best regards, Richard Harrison, KB5WZI

Nope, if he had a concealed carry permit, his behavior would probably
have been akin to my behavior, i.e. not criminal. Criminals rarely bother
with carry permits. In general, the good guys bother to obtain carry permits.
The bad guys don't. The good guys bother to obtain carry permits because of
the bad guys.

Surplus Sales of Nebraska carries a heavy duty expensive one. Lowe's
Hardware in Bryan, TX carries some light duty ones suitable for 100W
operation. They are with the special stuff like nylon washers, bolts,
and nuts, and brass/stainless steel hardware. I access that special
stuff section quite often. They have the 3/8x24 threaded stuff there.

Correct, we can deduce that the load is a 3:1 mismatch.

> Your graphic shows ALL of the power reflected from the load to be
> re-reflecting, and adding to the source power at the 3:1 mismatch in the
> line.

Yes, that is characteristic of a matched system. Zero reflected energy
flows into the transmitter. That means all energy from any and all
reflected waves is re-reflected back toward the load. There is simply
no place else for it to go.

> Questions:
>
> 1) Why doesn't the "Rho = 0.5" (correctly) shown on your graphic for your
> line mismatch correspondingly allow 25% of the power reflected from the
> load to pass through the mismatch to appear at the source? If Rho is less than
> 1.0, by definition the transition must pass _some_ power (25%, in this
> case).

Not 25%. It does allow 75%, Pref2(1-Rho2)=25W, of the 33.33W of reflected
power from the load to pass through the mismatch but it immediately encounters
Pfwd1(Rho2)=25W traveling in the same direction with equal magnitude and
opposite phase so Pfwd1(Rho2) and Pref2(1-Rho2) cancel, i.e. the sum
of their voltages is zero and the sum of their currents is zero. That's
how Pref1 gets to zero watts. But the energy in those canceled waves
cannot cancel and must change direction, i.e. be reflected. There is
simply no place else for it to go.

> 2) Same as 1 above for power arriving at the line mismatch from the
> source.

Pfwd1(Rho2)=25W is the part of Pfwd1 that is reflected by the impedance
discontinuity. It is covered in my last statement above.

> 3) If the line mismatch reflects reverse power coming back from the load,
> should it NOT also reflect power arriving from the source? Yet your
> graphic shows none.

This graphic is from web pages that explains everything. The top web page is:
http://www.qsl.net/w5dxp/waves.htm

> In summary, in your graphic the mismatch in the line behaves differently
> for power it sees from the source and from the load. From the source, it.
> reflects nothing. From the load, it reflects everything.
>
> Could you please explain this?

It doesn't behave differently. An impedance discontinuity is symmetrical. According to the superposition principle, Pfwd1 and Pref2 break down into unreflected, reflected, and re-reflected components as follows:

Pfwd1 = Pfwd1(1-Rho2) + Pfwd1(Rho2) = P1 + P3

Pref2 = Pref2(Rho2) + Pref2(1-Rhop2) = P2 + P4

P1 = Pfwd1(1-Rho2) = 75W (unreflected)

P3 = Pfwd1(Rho2) = 25W (reflected)

P2 = Pref2(Rho2) = 8.33W (re-reflected)

P4 = Pref2(1-Rho2) = 25W (reflected)

The reason that nothing is reflected toward the load is that the rearward traveling waves containing the energy components, P3 and P4, are equal in magnitude and 180 degrees out of phase and thus the sum of their voltages and currents cancel to zero because of destructive interference. Since energy cannot be destroyed, this wave cancellation causes a constructive interference of 50 watts in the opposite direction. Since the two waves involved in this interference are *reflected* waves, the constructive interference is *re-reflected* energy. The controlling equations are:

Pref1 = P3 + P4 - Interference Energy (destructive)

Pfwd2 = P1 + P2 + Interference Energy (constructive)

The sign of the Interference Energy indicates whether it is destructive or constructive, (-) for destructive and (+) for constructive.

If (Pfwd1 > P1 + P2), the interference on the load side of the discontinuity is constructive and therefore (Pref1 < P3 + P4) by the same amount, thus indicating destructive interference on the source side.

If (Pfwd1 < P1 + P2), the interference on the load side of the discontinuity is destructive and therefore (Pref1 > P3 + P4) by the same amount, thus indicating constructive interference on the source side.

If Pfwd1 = P1 + P2, there is no interference and Pref1 = P3 + P4.

The impedance discontinuity is symmetrical. Destructive interference on one side of the discontinuity is always matched by constructive interference on the other side. In fact, the migration of energy across the impedance discontinuity is what makes matching possible. No migration of energy equals no match.

Richard Clark wrote:
> We have TWO separate topics?

Yes, we do, Richard. The two topics are:

1. Wave interference between two coherent waves traveling in opposite directions in a transmission line, i.e. between a forward wave and a reflected wave.

2. Wave interference between two coherent waves traveling in the same direction in a transmission line, i.e. between two forward waves or two reflected waves.

Wave interference between a forward wave and a reflected wave is relatively easy to understand. When the voltages add, the currents subtract, and vice versa. That means when we have destructive interference between the two voltages, we have a corresponding constructive interference between the two currents. When we have constructive interference between the two voltages, we have a corresponding destructive interference between the two currents. The opposite direction of movement between total voltage and total current automatically keeps the energy equation balanced.

The difficulty that you and others seem to be having is in understanding what happens between two waves traveling in the same direction in a transmission line. The voltages have the same phase and the currents have the same phase so vectorially adding them results in an overall increase or decrease in energy in the resultant wave (except when the two waves are orthogonal to each other).

An increase in energy when two waves are vectorially added must be accompanied by a decrease in energy elsewhere. A decrease in energy when two waves are vectorially added must be accompanied by an increase in energy elsewhere. The conservation of energy principle will not allow anything else to happen.

If the angle between two phasor voltages/currents is less than 90 degrees, their vectorial addition will result in constructive interference. That constructive interference must be accompanied by an equal magnitude of destructive interference. In a transmission line system with an impedance discontinuity, if constructive interference occurs on one side of the discontinuity, an equal magnitude of destructive interference must occur on the other side of the discontinuity.

If the angle between two phasor voltages/currents is 90-180 degrees, their vectorial addition will result in destructive interference which must be accompanied by an equal magnitude of constructive interference on the other side of the impedance discontinuity.

> Write again, later, when you find a collaborator who understands you.

I'm working on that, Richard.

I am trainee Engineers on High Power Transmitter station.
My question is;
"How radiation resistance of uninstalled monopole antenna of high
power transmitter (say 100kwatt)is practically determined with help of
antenna structure?"
And second part of question relative to the first is;
"For the matching purpose specifically about AM High Power
Transmitter what would be Design of ANTENNA TUNING UNIT?"

These sound like test questions.
Are they questions you pursue out of knowledge, or are they ones posed as part of an examination?

Note to group: its finals time FYI.

FWIW. I've heard that it has gain on receive. Personally not sure. But, have
been using a 300-ohm twinlead J-Pole, at 30 feet high, for almost 10 years
in a PCV pipe, with no complaints or problems.

4738. Simple horizontal antenna advice II

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-15 16:34:53 UTC
From: Steve <no.sp@m.please>
Message-ID: <ja2L9.1621$Om2.220706@newsfep2-win.server.ntli.net>
Source record: 129076

(Apologies if this post is duplicated - my main ISP's NTP server seems to be faulty)

Hi,

Thanks for everyones advice on my last post a few weeks ago.

I've since constructed the longest dipole I could install and fed this this with homebrew 600 ohm feeder (6 inch spacing). The full length of the antenna is 120 feet with it sloping from 30 feet down to about 15 feet. The feeder is approx 60 feet long.

Whilst the antenna seems to load up OK (certainly on 40, 20 and 15) I'm wondering if my installation could be improved. The shack is in the converted attic and one end of the antenna is attached to the chimney. Therefore, the feeder leaves the feedpoint, drops a few feet and then rises again to enter the shack. The feeder almost runs parallel to the antenna with it being offset by about 6 feet as it enters the building.

Clearly the feeder in such proxity to the antenna will affect the performance but to what degree? I'm wondering if it is worth a) extending the feeder so the "sag" is greater or b) letting the feeder drop and putting a remote balun in, feeding the ATU with coax?

Thanks for any advice,

Steve M3ZQO

Tom, it bothers me that permits are issued in most states (including my own) without a comprehensive education requirement. Anyone who's trained properly knows at a visceral level that brandishment is a cardinal sin--and that only a suicidal nutcake would consider it.

Unfortunately, as Cecil suggests, those with the poorest impulse control rarely seek training or permits. Hell, it's not rocket science! Who has the time or patience for hours of tedious classes and all that stupid paperwork?

The more proficient citizen handgun owners I know typically read a lot, spend an hour or two at the range every month, and periodically attend a proficiency workshop (SIG Arms, LFI, etc). NRA isn't much help. Despite a very successful Hunter Safety Program, I think they've dropped the ball on defensive handgun training for adults. I'd like to see less political grandstanding and more grassroot effort at training.

In the end, though, when it comes to avoiding carnage on the highway, I'd feel far safer with a hand-held noise generator that terminates cellphone communication over a 1/4-mile radius than I would with a clammy handgun stuffed in my shorts that's pointed straight at my private parts. You gotta use your head and choose the right tool for the job!!

4742. Re: Windom Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-15 16:59:00 UTC
From: N4LQ <N4LQ@igLou.com>
Message-ID: <3dfcb4b5_2@news.iglou.com>
Source record: 129080

Use the modern version Windom with coax and 4:1 balun feed. I use one cut for 160m fed with RG-213 and a 4:1 current balun at the feedpoint. I put a 10 turn loop of coax at the base of the tower to help reduce RF on the shield. Results are fantastic. I have a tiny bit of RF in the shack showing on my field strength meter but only on 160m. All other bands are totally free of any RFI. SWR is low enough on all bands, except 30m, to get buy without a tuner making band hopping quick and easy. No switches to flip or knobs to crank.
My Windom is about 270ft long and resonates toward the lower end of 160 and 80m. If you cut it for the higher end of those bands, it will miss the higher bands and a tuner may be required for all high bands. Since I op mostly cw, this worked out great for me.
This antenna is at 60ft height at the feedpoint on the tower. The short end goes to a tree and the long end has a 45 degree bend and attaches to 2 trees all at 50-60ft heights.
I feed it .174 off center. Read the article by Cebik at:
http://www.cebik.com/gup/gup9.html
The feedline does tend to become part of the antenna. A "line isolator" beneath the balun might further help cool off the coax. I tried grounding the coax at various points and this influenced my tuning. Some experimentation will be needed with any installation. If you run into problems with RFI, try adding or removing some coax. The balun is available from Radio Works and is called the W2DU design. Don't bother trying to use the cheaper W2AU design. You will have problems on the higher frequencies with that one. I run 500 watts into the DU balun with no heating. It's questionable whether this balun can handle 1.5kw however.

Hi Muhammad,

This is relatively simple and generally covered within the first chapter or two of any antenna design reference. Consult Kraus as an eminent author on the subject. For the simple monopole of quarterwave construction it resolves to a figure in the mid 30's of Ohms (37 Ohms to pick a value) IFF there is a corresponding, well developed earth ground system, or if elevated, a ground plane.

There are two ways to determine, the empirical way, and the theoretical way. If the two answers do not converge, the difference is generally attributable to loss in the system (which includes that same ground mentioned). Either method usually boils down to observing the amount of current fed into the structure, at the feed point, and measuring the total radiated power. Not that difficult for a simple structure either way. There are other common commercial structures that are larger than quarter wave, but the methods are not that very different conceptually.

There is nothing inherently different between an antenna designed for amateur use and commercial use except for the concerns of a commercial operation requiring much more robustness (generally for continuous duty, every day for decades). The differences are also revealed in bandwidth, but that goes beyond the scope of your question.

Check out the all-HF-band dipole on my web page. It is about the
same length as yours and uses 450 ohm ladder-line as the feeder.
You will get a better match with your feedline at about 100 ft.
You can get a near perfect match if you vary the length of your
ladder-line using a method similar to mine.

Steve,
Having the feed line parallel the antenna for any length
isn't exactly the 'best' idea in the world. But, that depends
a lot on what you have available to work with. Making the
feed line 'sag' more may help, and naturally, having it come
away from the antenna at a right angle would be 'more better'.
If you have the extra feed line to play with, why not see what
happens? At the worst, you can always shorten it again.
'Doc

According to Title 10, USC, section 311, pretty much all of us are in
the "unorganized militia". Paragraphs A and C are the relevant ones.
Also, contrast the Ninth Circuit's decision with the Fifth Circuit's
finding that it is indeed an individual right, the Emerson case. Hmm,
sounds like the SC is going to have to deny certiorari to both in
order to continue to evade this "hot wire" issue.

Chuck,
If you compare two 1/2 wave length antennas of the same
polarization, at the same height etc., will one have any
gain in relation to the other? It doesn't really matter
'where' you feed them, from one end, from the middle, or
if you bent one half of the antenna around and feed it like
a 'J'-pole. Does it?

I agree that everything equal, there won't be a difference. I was just reporting what I had been told. BTW, the other fellow swears it gives 3db gain on receive. kinda hard to believe that it would show gain on receive and not on transmit. I could be wrong, antenna design isn't my best subject (and I hope to learn more)

Ah yes progress. We're spending $50*10^6 to put in this interchange,
the sole purpose of which is to make it easier to transition from I-10
to I-19.

"Interstate" 19, despite its nomenclature actually isn't "interstate"
but "intrastate", unless of course, your considering the state of
Sonora in Mexico. This 65 mile (oops sorry--100 KM) long highway from
Tucson to Nogales is projected to expand from 4 lanes to 10 lanes in
the future.

Your tax money working to make it easier for unsafe Mexican trucks to
haul produce and drugs to the USA.

But returning to topic.

I would never use a knife switch in a transmission line that is
operating in this frequency range, especially coax.

Any estimates of increased loss are wild leaps of imagination. At the
upper end of the frequency range, the switch is an appreciable
fraction of a wavelength long, and being non-coaxial, is more than a
slight impedance bump.

I don't use them on coax, only on "450" ohm ladder-line. The spacing
on the ladder-line is about 3/4" and the spacing between the knife
switch conductors is about 5/8". I am not aware of more than a slight
impedance bump using ladder-line.

Hi,

Try the half square for two meters, you can build this fast and for a few
dollars
or less if you have some # 12 thhn wire and some pvc pipe around.

http://www.cebik.com/hs.html

Dr. Cebik has a wealth of information on his web site.

You can build more antenna after you get on the air !

73

Enjoy your antenna.

> Best regards, Richard Harrison, KB5WZI

Thats my point. They used a system that is balanced for the antenna,
feedline, etc. Makes things easy. No ground needed at the antenna
being it's balanced and complete, and I bet the ground at the shack
was more to do with lightning protection and insuring all pieces are
at the same potential, rather than trying to cure a common mode or
"rf" in the shack problem . Nothing really to cure with their setup
assumming all is balanced. I'm glad my transmitters aren't that
big...:/
I have enough problems moving my henry console around. I had to bring
it here in the back of a truck. It wouldn't fit in a car either
without banging it up. My next amp will be solid state I'm fairly
sure. I want a little 500w solid state job to go with my 706. I'll
have a portable high power station that fits in two pistol cases, and
runs off battery power. Probably two or three batteries at that...One
for the rig, and two for the amp.

I am a member of the unorganized militia as defined. I would suggest you look up the term. Next the Constitution says nothing about being a member to have arms. It does say that because we need a "well regulated" (Meaning guns that have been sighted in and ready for use) militia. It was necessary for all men to have the right to keep and bare arms.

A few quotes are in order...

"I ask, sir, what is the militia? It is the whole people, except for a few public officials."
-- George Mason, 3 Elliot, Debates at 425-426.
"A militia, when properly formed, are in fact the people themselves ... and include all men capable of bearing arms."
--Richard Henry Lee, Senator, First Congress, Additional Letters from the Federal Farmer(1788)

"Whenever governments mean to invade the rights and liberties of the people, they always attempt to destroy the militia, in order to raise an army upon their ruins."
--Rep. Elbridge Gerry of Massachusetts, spoken during floor debate over the Second Amendment, I Annals of Congress at 750, August 17, 1789.

"The militia, when properly formed, are in fact the people themselves. ...(T)he Constitution ought to secure a genuine (militia) and guard against a select militia, by providing that the militia shall always be kept well organized, armed, and disciplined, and include...all men capable of bearing arms..."
--Richard Henry Lee, writing in "Letters from the Federal Farmer to the Republic," (1788) p.169.

To suppose arms in the hands of citizens, to be used at individual discretion, except in private self-defense, or by partial orders of towns, countries or districts of a state, is to demolish every constitution, and lay the laws prostrate, so that liberty can be enjoyed by no man; it is a dissolution of the government. The fundamental law of the militia is, that it be created, directed and commanded by the laws, and ever for the support of the laws.
---John Adams, A Defense of the Constitutions of the United States 475 (1787-1788)

"Who are the militia? Are they not ourselves? Is it feared, then, that we shall turn our arms each man against his own bosom? Congress shall have no power to disarm the militia. Their swords and every other terrible implement of the soldier, are the birth-right of an American ....The unlimited power of the sword is not in the hands of either the federal or the state governments, but where I trust in God it will ever remain, in the hands of

the People."
--Tench Coxe, Pennsylvania Gazette, Feb. 20, 1788.

"We will not be driven by fear into an age of unreason if we ... remember
that we are not descended from fearful men, not from men who feared to
write, to speak, to associate and to defend causes which were, for the
moment unpopular."
--E.R. Murrow

"The militia is the dread of tyrants and the guard of freemen."
--Gov. R. Lucas, former Major General of the Ohio Militia, 1832

"The United States should get rid of its militias."
-- Stalin, 1933 (btw, Stalin killed 20,000,000 of his own citizens!)

"As the greatest danger to liberty is from large standing armies, it is best
to prevent them by an effectual provision for a good militia."
--James Madison, notes of debates in the 1787 Federal Convention

"The signification attributed to the term, Militia, appear from the debates
in the Convention, the history and legislation of Colonies and States, and
the writings of approved commentators. These show plainly enough that the
Militia comprised all males physically capable of acting in concert for the
common defense... And further, that ordinarily when called for service these
men were expected to appear bearing arms supplied by themselves and of a
kind in common use at the time."
--US Supreme Court, US v Miller 1939

"In the beginning of change, the patriot is a scarce man; brave, hated and
scorned. When his cause succeeds, however, the timid join him, for then it
costs nothing to be a patriot"
--Twain

.

> 'Doc

Haven't really nailed that one down yet,
However I believe the stub pulls the radiation pattern towards the ground,but
also the antenna exhibits a fair amount of front to back.
I raised mine up 8 more feet and coundn't figure out why a repeater
I was hitting 80 miles away with 5 watts now took ten,thought maybe the trees
were affecting the swr,checked that,it was ok,but while I was up there I
figured I'd tweak it. About fve up and downs with the thing my repeater reports
conflicted with my swr readings.
I smoked a cig and scratched my head, noticing the orientation was
different then when I first put it up. I spun that baby around to where I had
it originally and low and behold I was whacking the repeater full queting on
only 3 watts. Next step is to set the baby up in an open field and try to plot
the prop. pattern with a FS meter and a step ladder.

CAM wrote:
"The difficulty that you and others seem to be having is in
understanding what happens between the waves---."

Consider a lossless line carrying a wave. the incident wave makes a
voltage and a current. Everywhere on the line, the incident volts
diviided by the icident amps poduces the same ratio, Zo.

If the incident wave encounters a mismatch, part of the incident energy
bounces, creatting a reflected wave, traveling back towards the source
of the incident wave. This wave has a polarity distinguishing it from
the incident wave. The reflected wave has its volts and amps
out-of-phase. They are 180-degrees out.
The reflected wave`s voltage to current ratio must, like the incident
wave, equal to Zo, but in the reflected wave the sign is reversed, and
the ratio is -Zo at the load. (formula 4-11, Terman 1955)

Terman says ---"the reflected wave on a transmission line can be
described as a voltage accompanied by a current proportional to the
voltage flowing away from the load---."

Terman says the incident wave must satisfy Zo at the load. Terman says
the reflected wave must satisfy -Zo at the load.

Terman says the load voltage must equal the sum of the incident ad
reflected voltages.

Terman says the load current must equal the sum of the incident and
reflected currents.

Terman says the vector ratio, E-load / I-load , must equal Z-load. Those
are not minus signs.

The vector ratio of the reflected volts to the incident volts (can`t
exceed 1, obviously) is called the load`s "reflection coefficient". It
has both magnitude and phase. Reactance may be part of the load.

In a lossless line, the refection coefficient is a constant amplitude
anywhere on the line ff there are no other impedance bumps. A lossy line
would cause attenuation of the reflection, and growth of the incident
wave, in checking points closer to the original source.

If no directional coupler is used to separate forward and reflected
waves, sensing will
include a composite of both waves.

In a good transmsson line, Zo = sq. Rt. L/C. The incident and reflected
waves see the same Zo as it represents the same impediment coming or

going. At r-f, Zo is independent of frequency over a huge range.

As a wave takes time to travel a particular length along the line, and the phase rotation of the source continues to advance during the travel time, a given point on the traveling wave is being shifted in phase from the voltage and current at any instant at the source.

On open-wire lines, waves usually travel near the speed of light. On coax, speed may be only 2/3 the speed of light, or it may be some other fraction.

Terman says that in the case of a line with an open circuit, the reflection coefficient is 1 on an angle of zero. That says that the reflected wave is equal in magnitude to the incident wave and the reflected volts have the same phase as the incident volts. These volts add together arithmetically. They double at the open-circuit from the magnitude of the incident volts. Eload = 2Eincident. We used to call this the "Ferranti effect". The incident and reflected currents are also equal, but they are out-of-phase, so they cancel. Their energy isn`t destroyed but tranfers momentarily to the E-field as represented by the doubled voltage at the open-circuit. A short distance back from the load (open-circuit), normal voltage and current reappear. The varying electric field is able to generate a new magnetic field, and vice versa.

Waves traveling in opposite directions remain separabler by using a directional coupler. This proves energy moves in both directions with no mutual distruction.

Taken together, the waves make the familiar SWR patterns. Current is shifted 90-degrees from the voltage. Current and voltage patterns repeat in every half-wavelength along the line. This results from the velocity at which the waves pass through each other when traveling in opposite directions. It`s double that of either wave. Voltages add where currents subtract and vice versa.

Terman explains what happens with almost any imaginable load, short-circuit, matched, reactive, etc. He tells it better than I can.

Terman says that: "----irrespective of the relative amplitudes of the incident and reflected waves, the phase of both voltage and current will advance pi radians (180-degrees) when the distance toward the generator decreases by a half wavelength."

In a lossless line with an open or a short, voltage and current distributions form half-sinewaves that go to zero at the minimums. The zero points for volts correspond to current maximums. This is a temporary shift of energy to the H-field. Each H and each E field of a wave carries half the energy in the wave. Twice the single-field energy temporarily contained in the other field is still an unchanged total energy.

The incident wave at any point has a non-varying power level The reflected wave also has a non-varying power levell.

At any point the incident and reflected waves are traveling in opposite directions. This shows in the Bird equation for power extracted from the source and delivered to the load. It`s the difference between incident and reflected powers.

This means the forward and reflected powers are in opposition everywhere, including at the source.

Therefore, an opposing reflected power is rejected by the source and re-circulates in-phase with the newly emerging power.

Best regards, Richard Harrison, KB5WZI

Richard, here's my entire statement to another Richard.
"The difficulty that you and others seem to be having is in
understanding what happens between two waves traveling in the
same direction in a transmission line."

I don't see that your posting addressed what happens when the two
waves are traveling in the same direction. You speak of forward and
reflected waves. The question is: what happens when two reflected
waves encounter each other?

Quotes to the meaning of militia are a prime example (from the Oxford
English Dictionary which offers the historical meanings of the words
as they were used at the time cited):

Militia 1590.
1. A system of military discipline, organization,
and tactics; the arts of war - 1678.
B Military service; warfare - 1685.
2. The control and administration of the military and
naval forces of a country - 1647.
3. A military force; in later use a 'citizen army' as distinct
from a body of professional soldiers 1590.
4. A branch of the British military service, forming a part of
'the auxiliary forces' as distinct from the regular army. Also, a
similar force raised in British North America. - 1659
B. U.S. The whole body of men legally amenable to military
service 1777.

Army Middle English
1. An armed expedition by sea or land. - 1525
2. generally An armed force (by sea or land) - 1460
3. specifically A. A naval force; an armada, a fleet - 1786
B. A land force; a body of men armed for war and organized in
divisions, and regiments under officers and a Commander in Chief
or General. - 1557

If there is one compelling and over riding difference between the two,
it is not in the nature of arms, but rather in the nature of
composition, assembly and purpose of men under arms.

Historically, Armies were rarely composed of farmers, merchants,
craftsmen, or other townsmen. Frequently, they were professional men
at arms, fighting not for a government, but for themselves on the
terms of their contract under a noble or other titled person who had

the means to pay them the cost of that contract. One obvious correlation is found in our history and our having fought the Hessians, a Germanic region that supplied such contract warriors to Britain for the purpose of overthrowing the rebellion. In fact "Armies" at that time often meant a foreign troop assembled under a leader not of their nation. National Armies is a recent invention, particularly of Napoleon I. In today's political climate, that could be likened to the U.N.

By the definitions above, the militia was well-regulated in the sense of being available to the government's direction to mount a defense against a foreign invasion AKA Armies (such as we perceived the British to be after 1776) there was no other purpose as we had no regular or standing Army of our own. The militia was a voluntary service, unpaid, and trained through the device of meeting regularly for exactly that. The United States Army, for the period and many years after the dates of your early quoted material, consisted of very few men who served with pay or were provided arms, uniforms, tents, or supplies (the militia was expected to take care of its own needs so as to not encumber the government with demands for taxation or levies). Also during the period of your quoted correspondence, there were fewer than a dozen trained military officers and almost no soldiers and absolutely no sailors nor naval officers (in America, the Army is the Senior Service - in Britain it is the other way around - and the U.S. Navy was formed shortly after this same period of the early correspondence you quote AND after the U.S. Marines).

Hi Fred,

Thanx for your conspicuous research and honest reporting.

In recent headlines:
"Budget delay may hold up work on vets' benefit claims"

"Half of Americans don't want their kids to be soldiers..."
quoted from that source:
"The most privileged and educated in American society now don't
regard military service as something honorable or useful."

Having performed my service, as did my father, my mother, my
grandparents and generations before; such an attitude cultured by ALL
administrations combined of the past 50 years is abhorrent.

I wrote:
"This means the forward and reflected powers are in opposition
everywhere, including at the source."

Think of a reflected power lowering the load impedance seen by the
transmitter.

If the transmitter had been matched to Zo, lowering the load it sees
reduces the power output. This lowers the reflected power too.

Raising the impedance spoils a match too.

If you have two windings on a transformer phased as you would for
parallel connection, and connect them, they don`t exhibit much current
exchange if they are well balanced.

Place a resistor between one of the terminals on each winding
representing the same polarity. Again the current flow will be from the
winding with the higher voltage through the winding with the lower
voltage. The voltage drop across the resistor comes from the difference
in voltage between the two source coils. The current flows from the
higher voltage coil into the lower voltage coil.

You have a transmitter output which is always equal or more potent than
the reflection.
If reflection and the length of line makes the incident and reflected
waves phase-aiding at the transmitter output, seems we could fix that
with a 1/4-wave extension to our coax.

In any case, the reflection is not the source of power. The transmitter
is the source of power.

Best regards, Richard Harrison, KB5WZI

If the reflection voltage is 90 degrees out of phase with the transmitter
voltage, the reflection voltage will be maximum when the transmitter
voltage is zero. What happens at that point?

"I don`t see that your posting adressed what happens when the two waves are traveling in the "same direction" in a transmission line."

I remember from a lecture over half a century ago that said:"They merge."

Makes no difference because I think there is no way you could separate them for separate measurement. Two same frequency, same direction, same path waves are indistinguishable when both have current in the same direction.

Best regards, Richard Harrison, KB5WZI

Of course, they are indistinguishable after they merge. But they not only merge. Depending on their phase, they are likely to interfere. And if the two waves interfere constructively, there has to be an equal magnitude destructive interference. If they interfere destructively, there has to be an equal magnitude constructive interference. I remember spending a month on this subject at Texas A&M in the late 50's. Is this something that has disappeared from the EE curriculum in the past 45 years?

Let's take an easy to understand example involving a forward wave and a reflected wave. Those two waves interfere all up and down the transmission line. That's what causes standing waves. If the two voltages interfere constructively, the two currents must interfere destructively in order to maintain the energy balance. If the two voltages interfere destructively, the two currents must interfere constructively. In other words, if the total voltage increases, the total current decreases, and vice versa so that V*I*cos(phase_angle) remains constant.

However, the same rules do not apply to coherent waves traveling in the *same* direction. Something different from the above must happen to maintain the energy balance in that case.

CAM wrote:
"If the reflection voltage is 90 degrees out of phase with the
transmitter---?"

The obvious answer is the magnitude is given by the sq.rt. of the sum of the squares of the voltages. The angle between the resultant and the abscissa is arc tan ordinate over the ascissa.

(Some very good quotes deleted.)

Most people in America would be very much surprised to know that they're members of a militia. You should send those quotes to the Ninth Circuit Court of Appeals. They'll probably send you back an equal number justifying slavery from the same period. By the way, didn't Richard Henry Lee oppose the Constitution because it might destroy states rights? And didn't Elbridge Gerry originally refuse to sign the Constitution?
I suspect your interpretation is probably right concerning the Patrick Henry type's interpretation of the Second Amendment, and, if the Supreme Court ever gets enough courage to address the matter, they'll probably agree. No matter how they rule, however, there will be a lot of very angry people in America.

Hi, Richard,
you might remember that, during the Civil War, the well-off
could either provide a substitute or pay $300.00 to get out of the draft.
America has a long, rich history of the double standard.

Sure it has gain. About 100 db over a dummy load, 10 db over the rubber
duckey that comes with a HT and 0 db over a dipole.
You just have to know the refferance point.
Also an antenna will normally have the same gain on transmitt as it does on
receive.

That's news? Where were you during Viet Nam? No one denies our democratic republic is a big fat messy lumbering animal. However, if you really hate the fleas and dishevelment that much, there are plenty of places on earth where the populace have no guns and order is strictly maintained (flights daily from an airport near you).

Better yet, rather than getting those whitey-tighties all in knot, why not lease a new Beamer, jump on the highway, pick up your cell, and call someone you love? Get with the program.

Some of us in West Tennessee do. We use it as a messaging system (beats the heck out of no one on the 2-meter repeater at thet time), for weather reporting and bulletins. Besides it is still a lot of fun.

The point is that voltages 90 degrees out of phase cannot interfere
with each other, i.e. the reflected voltage will not even "know" the
forward voltage exists. So does that reflected voltage flow
through the transmitter? Does the reflected current flow through
the transmitter?

CAM wrote
"And f the two waves interfere constructively, there has to be an equal magnitude destructive interference."

Agreed that energy must balance so that after interaction its summation is unchanged or accounted for by another addition or subtraction of energy from the system.

An analogy is the spatial redistribution done by a directional antenna. Same power, but some places have more because some other places have less.

On a transmission line, energy interference leaves the waves almost unscathed as they pass through each other. The forward wave has different characteristics from the reflected wave, so they don`t merge.

Where SWR creates a maximum voltage, SWR also creates a minimum current. If the forward and reflected powers are constant over the length of a transmission line, the sumation of the forward and reflected powers are constant also.

Two or more waves of the same frequency coming from the same source are synchronized. On the same path, they have a fixed phase relationship and magnitude ratio. They decay at the same rate. If they don`t decay, the power of the combination is the same everywhere along the path. There is no SWR where no reflected wave is present and you only have a forward wave , no matter how many parts were used to build the wave.

Best regards, Richard Harrison, KB5WZI

Why do people go to all the trouble of a J-pole, when they could just hang a
little dipole vertically? (I'm thinking of building one or the other; the dipole
would certainly be easier.)

> Where SWR creates a maximum voltage, SWR also creates a minimum current.

Exactly true as explained in a lot of textbooks. However, for waves
that interfere when traveling in the same direction in a transmission
line, my meager library says virtually nothing. But the same principles
apply. If there's destructive interference, there must be a matching
constructive interference and vice versa.

When forward and reflected waves interfere, if there is constructive
interference in the voltages, that same amount of destructive interference
occurs in the currents.

When waves are traveling in the same forward direction, since the component
wave voltage and current are in phase, if the voltages interfere constructively
then so do the currents. If the voltages interfere destructively then so do
the currents. So we get either constructive or destructive interference from
those two waves. Whichever it is, at an impedance discontinuity, constructive
interference on one side of the discontinuity results in destructive interference
on the other side. Dr. Best and others seem not to understand this law of physics.

The J-pole is easier to feed and to mount at the very top of a metal pole.

CAM wrote:
"The point is that voltges 90 degrees out of phase cannot interfere with each other."

We have in the past had 2-phase power systems. Three or more wires were needed for distribution. Coils are perpendicular. Volts line to line are 1.414 times the coil voltage (line to neutral).

2-phase has gone away because it often needs more wires and is harder to balance than 3-phase power.

Two equal voltage vectors at right angles have (sq. rt. 2) times the motivating force on current that either vector alone would have. Sq. rt. 2 is the same as 1.414.

CAM wrote:
"Does the reflected current flow through the transmitter?"

The out-of-phase reflected voltage and current lead me to believe it doesn`t happen. I have been comfortable with assertions that reflected power is re-reflected at the transmitter, made long before I ever heard of a Bird wattmeter.

Bird says:
Transmitter power = Forward power - Reflected power.

If reflected power bounces on return to the transmitter, reflected current doesn`t flow through the transmitter.

If reflected power flows back into the transmitter, the current is still out-of-phase with the reflected voltage. How can that produce much dissipation? It takes a new reflection to correct the phase of the reflected power. If the reverse current reduces the output of the transmitter, the transmitter just has to crank out more to restore the desired output.

The only interest of this discussion must be academic, as we know the Bird formula works.

Best regards, Richard Harrison, KB5WZI

I'm sorry, I misspoke above. I should have said that voltages 90 degrees
out of phase cannot affect each other. Obviously, they can interfere, i.e.
superpose.

I had an e-mail which said re-entry of reflected power into a transmitter is not academic.

The transmitter is the source of the reflected power, too. Sending it out for a spell doesn`t greatly multiply its potentency.

What arcs and burns a transmitter is the changed impedance load on the transmitter caused by the reflection.

If the transmitter is unloaded, it may arc due to the lack of internal voltage drops.

If the transmitter operates into a short-circuit, it may draw too much current and burn.

Best regards, Richard Harrison, KB5WZI

Hi Rick,

Did you submit your life and freedoms to the Universal Code Military
of Justice? Officer or enlisted? Drafted, volunteer, or simply a
good lottery number?

How many patriots here "deferred" their service? Do any of you plan
to pay your obligation anytime soon? For such patriots, I would offer
that the meaning of "deferred" does not mean a free ride while the
suckers took it in the chops by charley.

So as to not confuse some with the history of language, Webster's
Dictionary reveals "deferred" to mean:
1. To put off until a future time, POSTPONE
2. To postpone the induction of one eligible for the military
draft.
To delay, procrastinate.

We have a local cartoonist for the OP-ED page who is asking the
question: "Would you let your child join the war against Iraq? Would
you join yourself?" The guy is one of those effete Right Whiners who
came to this ploy for selling newspaper while talking to a buddy
mixing Martinis at a cocktail party. What a whore.

To answer Tom, no, I am not surprised by the depth of insincerity by
those who walked away from obligation and who now wrap themselves in a
flag I volunteered to serve. They found the paths to power and money
while I served, and no doubt they are leveraging a way to put me
against the wall as a traitor to America if I in some way jeopardize
their income or their fantasies of having single handedly smashed the
evil empire from their DC office. The beltway is chock full of these
warm weather warriors and they have let us know that Veterans are not
a group they hold dear.

I fondly recall one correspondent here putting it so pithily "You
lost, get over it." ...I don't think so.

Hi Cam,
I have a real nice knife switch. It is spaced about 4" apart for the knives and is made from 1" x 1/8" copper. It is a dual set mounted on a 3/4" thick piece of what appears to be Bakelite. I have used it for various wire antennas and was wondering, does the width spacing affect the swr when used with a narrower ladder line?
BTW, look for these types of switches at demolition companies.
Thanks

Hi Fred,

It is the nature of the topic, certainly; and again, I have the
credentials (both academic and military) to respond with first hand
knowledge.

So as to remove any taint of being British in the nature of word games
I will offer a certified American source for definition from Webster's
(the first "American Dictionary of the English Language"):

Militia,
1. A military force that is not part of a regular army and is
subject to call for service in an emergency.
2. The whole body of physically fit male civilians eligible by
law for military service.

I would note there is not a jot of difference between English and
American meanings, and it is more evident that the early
correspondents were still on the same page with regard to meaning
either way. As for the historical context, this is something I
learned from attending Army lectures (open to army brats such as
myself) while I was pursuing a goal of finding admission to West
Point.

Hi Richard,

Kudos to that anonymous e-mailer. That our "sources" may not conform to Thevenin (or Norton for that matter) is of little consequence to a damaged wallet when some are swayed by crafted arguments proving there is no power in a reflected wave (except, uh, when we use a directional coupler, or, uh, circulator, or, uh....).

I can anticipate the argument of lumped equivalents of the line causing the same grief. I have no argument to their added Z complete with Q multiplying V's and I's, until we reflect (no pun) that nearly every argument offered is posed in terms of simple Resistive ratios. It is at this point that the absurd (the internal resistance has nothing to offer) has kidnapped discussion.

The complete antenna, can be grounded at dc potential. Lightning protection.

My twinlead J-Pole was just easier to mount an feed inside a PVC pipe and mounted above the TV Antenna.

Hi,

I recently pirchased the new Diamond HV7A quadband mobile antenna (6m, 2m,70cm, 10m) I have it at appros 1.2:1 on all bands except 6m.

The lowest I can get the SWr down to hear is about 1.7:1 I am using an antenna analyser to do the measurments.

If anybody has come accross a similar issue and has managed to resolve seam, I woukd appreciate if you could drop me a line.

Many Thanks,

Aidan EI5HW.

> Bird formula works.

Yes, by definition of the steady-state net conditions. It is certainly
of academic interest to know what actually happens in reality. If a
transmitter re-reflects all the reflected power, then why do we need
an antenna tuner which does exactly the same thing? If the transmitter
re-reflects all the reflected power, why is it so "unhappy" when it
"sees" reflected power?

But this discussion has virtually nothing to do with what happens at
a lossless impedance discontinuity in a transmission line.

Source record: 129044
Cross-posted to: rec.radio.shortwave,rec.radio.amateur.antenna

I live in an appartment, urban area (down town). My new YB-400 receives only strong stations (indoor) when I extend its built-in antenna, weaker stations are barely audible, and there is lot of noise, too. Reel antenna by Grundig which is included in the package, improves sensitivity a bit.

Someone told me an outdoor antenna may reduce noise(?) and improve sensitivity.

I am really radio illiterate, so all I can think off is a kind of small inverted-L antenna, 3.80m (12.46') long enamelled copper wire span on a top of a balcony ceiling which will be about 10 metres above a street.

Will this project help ? If so, should I use a bare copper wire or enamelled wire ? Do I need a tuner for the antenna to cover 11-90m bands ?

If this idea for reducing noise and improving sensitivity is useles, please suggest something that will work. A balcony is 390x30cm.

Are there any pre-built low cost outdoor stealth antennas which will help in my case ?

Thank you very much.

Candy,
An out door antenna should help to some degree,
but don't expect miracles. Your antenna should be
as long as you can make it. and as high as you can
get it. How you do that is very non-critical, so
do the best that you can.
Good luck...

It might be easier to just get their 19' telescoping, guyed mast, and use
something other than your chimney for the base. They also have a 36' size.

This has not been the experience in Michigan. Perhaps in States where beautiful people are able to receive a CPL without any demonstration of competency or training (including, recurring training) this could be a concern. As a group, the rate of crimes or infractions committed by CPL holders has been smaller than that of police officers. At least here, none of the handful of persons who have lost their CPL because of an infraction used a firearm in that infraction. (Forgetting to sign your car registration is such an infraction.)
Were you to experience the standard training course required, you would have a better understand of why Michigan CPL holders are unlikely to be in the news.
Some people are uncomfortable about the existence of CPLs. One source that I have found is the sincere belief that firearms are able to discharge by them selves. (I had a PhD mechanical engineer tell me this while simultaneously saying that it was irrational.) Another source comes from people who know, usually at a subconscious level, that they would use anything at hand to hurt others when they become angry or frustrated. It is understandable why they would expect others to behave in the same manner.

I agree with Mr. Harrison. Many years ago, working as an (under age) broadcast engineer at an AM station, I watched a Summer storm hit our towers. I watched out the window with my hand near (note: near) the breaker on the transmitter (pair of 813s modulated with more 813s) and when a particularly big surge would trip the breaker I would re-assert same. No damage to physical plant. Would do nasty things to mice in the meter rooms at the base of the antennas.
One can protect from lightning. Sometimes, it is expensive. 73

This is a follow up to my original post about the "Loop Skywire"
antenna.

I put it up today....it is sort of a narrow rectangle rather than a
square loop....I don't have a long tape measure so the size is a very
rough estimate.....approx 170' long by approx 50' wide (approx 440'
total). One corner is up approx 35'....the nearest opposite corner is
approx 20' up.....then it slopes down to approx 15-20 ft at the far
ends. Its what fits with the trees I have on my property. The feed
point is approx 45' from the corner on one of the long legs. I'm using
rg8x, no balun. I didn't even try to "model this but I just worked
Boliva and Argentina (Tierra del Fuego)using my K2 with autotuner at 5
watts....so I'm a happy camper as I had nothing to use on 20m before
today. I'll be trying it on 80 and 160 tonite but may have to adjust
the feed line length to get a better match....the way it is I only get
4.7-1 on 160, but it does 1.2-1 on 80.

Because you are living about 10m above ground level, you could try to hang down a vertical isolated wire at the rear side with the agreement of your neighbours (pay attention to electrical safety), just for trying. Maybe it could also give beter signals. You can hide the wire later. Both solutions (horizontal and vertical) will not give the same results but an outdoor antenna should be beter.

Noise level is a function of bandwidth but how can we design a tuner for such a wide frequency range and a random impedance situation ?

Chuckle. Reminds me of my first day on the job as a broadcast engineer -- my mom had to give me a lift because I wansn't old enough to get a driver's license. . . I fired up the transmitter in the morning, ran a canned show all day, and shut it down at night. Got some good stories from those days at the transmitter shack behind the cemetery in the middle of a cow pasture in Golden. Lightning didn't bother the old Gates BC-1, either. Sometimes it would groan and the lights would get momentarily bright when the lightning hit the power line nearby, but I don't recall it ever being knocked off the air.

Yes, the width of the two 'knives' will make an
impedance 'bump' in the feed line. IMpedance would
be higher than for the narrower 450 ohm line. Just
depending, it would probably make no 'big deal' at
all.
Actually, what I should have said was, yes it makes
a very big impedance 'bump' that will totally scew up
the impedance match at the transmitter. What you really
should do is send me that switch. To show you how
generous I am, I'll even pay half the shipping.
'Doc

PS - I got a feeling that this isn't gonna work...

What time of day do you listen? 49 meters is definately a night time band.
41 tends to be that way, and the other two are probably best heard in the
afternoon, although night time reception might be good if the solar flux is
high enough. Try getting 10 or 20 meters of antenna wire out the window.

According to Butternut, there is none. One is just a newer "model
number" number than the other. Unfortunately not all dealers have
updated their catalogs.

FYI, I love mine!!!!!!!!!!! Haven't had a bit of trouble with it
(tuning or otherwise) while a buddy of mine from work has a comparable
GAP, and he has nothing but tuning troubles.

You never did say what you had in mind, just that car dealers use balloons for advertising and you once messed around with a wire recorder. I'm going to assume that you are contemplating raising a wire by balloon and using it as a two meter antenna. It should work quite well as long as your intended contact is somewhere in outer space. It would be quite directional. Strait up.

CL,
As long as you took proper precautions with the baloon
I don't see why it wouldn't work. If the baloons you're
talking about are the 'blimp' type, I would think they
would hold a pretty fair weight load. I would also think
that you would be using cable to tether the baloon that
was quite a bit more than just wire (how about 1/4 air-
craft cable or larger, depending on the baloon of course).
Also depending on how the tether was made, you could
probably load the cable as an antenna. Not really sure
how well that long of a 'longwire' antenna would work at
VHF (impedance matching problems), but you ought to be
able to hit the local repeaters easily!
Safety is the primary concern. There should be a
number of articals about 'baloon antennas' for HF, but
the same safety 'rules' apply.

N1RZB,
They work fairly well as a receiving antenna, but
not well at all for transmitting. QST had an artical
about them a number of years ago...

good for a 160 or 80 meter...
at multiple 1/2 waves where a good ground is not as important...
but the wire should be copper or copper clad...
as I recall recorder wire doesn't rust so I'd guess its resistivity is
pretty high!
now give us clearer picture of what you'd do on 2 meters!

Never had a transmitter go off the air due to a lightning strike. (Just lucky) But, the old Collins V20-1 (I think it was a V20) went dark one morning. We had a large snake in the cabinet, in the PA coils. We were cleaning fried snake out for months, and as far as I know there might still bet pieces left.

Thank you all, gents. The knife switch I had in mind has two blades, DPDT, spaced about 3 inches apart, made out of heavy copper and mounted on a white glazed ceramic base. Perfect to open and ground open wire transmission line. Hard to find anymore but will check out your suggestions.

This is going to sound like a joke but it's not. The FAA requires that you file a flight plan before flying any tethered balloon that contains more than 105 feet of gas. This rule is widely ignored but could come up if an accident were to happen.

Wow! We also had a Gates transmitter, but I have no recollection of its model number. It is possible that I had a driver's license, but I took myself out to the transmitter/studio by bicycle. Certainly did not have a car. In the early morning, I would sometimes buy a bottle of milk from the delivery man (another trade that has disappeared.) and have a big breakfast while playing one of those huge disks that were adds for the military. The man who owned the station was also a Scot and knew not to ask the wrong questions: "lets see your first phone license" "you may start at sunup and work 'till sundown" License at that time did not have age marked on it. Had to have my Mother cash my pay checks as I was working when the banks were open. My what an education that job provided.
Had a DJ who insisted on turning up the clipping limiter. Could not get him to keep his hands off of the control. One night, took the control off the panel and replaced it with a dummy pot.
There were even stories of 160 meter operation after signoff......
Opportunities like those seem not to exist today. Sad. 73 Mac

Hi Candy,
a random wire, nearly horizontal, as long and as high as possible,
seems to be the simple solution. No tuner is necessary for receiving,
but a simple matching LC circuit (dowload SELECT_1.EXE from Reg
Edwards G4FGQ, http://www.btinternet.com/~g4fgq.regp/page3.html#S301)
can improve both the selectivity and sensitivity. Do not forget about
a good RF grounding of your receiver. And employ some lightning
protection: disconnecting the antenna and throwing its lead out from
the balcony when you don't operate seems to be the simplest.

4865. Uncertainties on F/B- and F/R-ratio

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-17 10:59:08 UTC
From: 4nec2@gmx.net
Message-ID: <ee90361b.0212170259.58aa4ddd@posting.google.com>
Source record: 129002

Hello...,

For some time now there are a few questions in my mind for which I did some theoretical assumptions.

Front to back ratio (F/B) is specified as the difference (in dB's) between the gain for the main lobe and the gain in the opposite (+180 or -180 Azimuth-degrees) direction. (Free space assumed)

What about the F/B ratio for directions not equal to the main beam direction ? Is F/B ratio now related to the direction opposite to the direction of interest or is F/B ratio only used in conjuction with main-beam direction ?

Furthermore how exactly is F/B ratio specified when ground is involved and the main beam is pointing upwards for lets say 30 degree elevation. Is it appropriate to get the backward gain also for 30 elevation but with 180 degree azimuth difference ?

From the theorectics, Front to Rear (F/R) ratio is specified as the difference between gain for the main lobe and the gain for the maximum lobe in the backward half of the pattern. So for angle-difference from 90 to 270 degrees to the main beam direction.

My next question, should the whole backward half of the 'radiation-sphere' be considered or is this restricted to just the horizontal plane ?

Finally how is F/R ratio specified when ground is involved (main-beam points upwards) or when a direction, not equal to the main-beam direction is considered ?

I hope someone can give me a more final answer to my uncertainties...

Arie.

> canned show all day, and shut it down at night. Got some good stories

My first day (at an FM station) started with instructions on how to read the "frequency meter" quickly, because it changed so fast!

It was a school station--on the air from 4 PM to midnight. We had two of the large Ampex tape machines (the most expensive things in the place) with nice remote controls. I went on the air by playing standard tapes for 30 minutes, by which time "real people" were supposed to arrive. The tapes were so brittle that they often broke in the first minute or so, leaving dead air. I usually grabbed whatever record appealed to me and put it on while fixing the tape.

The transmitter (5 KW ERP; don't remember the actual power) was an antique; it had a wheel as large as a car steering wheel to "bring up the voltage". The year after I left, the FCC inspected the place and the school (which I shall leave unnamed) suddenly bought a considerable amount of new equipment.

It was a nice student job --- take the transmitter on and off the air, read the meters, and keep the transmitter log. (I usually filled in the log the next day, "by memory".) It was the only job where I used the "P1" license; have never used my "T2" and probably never will considering the changes in ship radio requirements.

Varying the length of 50 ohm coax won't appreciably change the 50 ohm
SWR unless the coax is very lossy. If you want to use a tuned feedline,
it needs to be something besides Z0=50 ohms.

4873. Re: Uncertainties on F/B- and F/R-ratio

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-17 15:02:05 UTC
From: k3bu@aol.com
Message-ID: <20021217100205.07110.00000203@mb-mu.aol.com>
Source record: 129011

Hi Arie,
thanks for work on the 4NEC2, I have not had the chance to play with it yet, but let me try to shine some light on the subject of your questions from the serious user/contester point of view:

>Arie writes:

>For some time now there are a few questions in my mind for which I
>did some theoretical assumptions.
>
>Front to back ratio (F/B) is specified as the difference (in dB's)
>between the gain for the main lobe and the gain in the opposite
>(+180 or -180 Azimuth-degrees) direction. (Free space assumed)
>

I think this spec is carry over from the days when things were simple, antennas with single driven element which exhibited major lobes at 0 and 180 deg, that's where F/B comes from. It was the major indicator of the antenna's performance.

>What about the F/B ratio for directions not equal to the main beam
>direction ? Is F/B ratio now related to the direction opposite to the
>direction of interest or is F/B ratio only used in conjuction with
>main-beam direction ?
>

Then when the dual driven elements, like in ZL special, HB9CV and other designs came to play, the "F/B" became almost infinite due to the cardioid pattern, which exhibited deep null in the 180 deg direction, but had two lobes off the back half. Technically those lobes should not be called F/B, practically they are in the "back" or rear half of the pattern) in order to distinguish it from "pure" F/B of 180 deg. More appropriate is the term F/R - front to rear, implying that we are looking for the ratio of signal strength between the main lobe at the front 0 deg. versus max lobes in the 90 to 270 deg "rear" half. The proper representation of the antenna's "F/B" should be really the volume of the front lobe (270 - 90 deg) vs. all rear lobes (90 - 270 deg). This is if we are interested in the overall performance of the antenna and its "back" or "side" rejection properties (in addition to gain figures of major lobes). For contester there is a split in desired TX and RX antenna performance: for transmit we want to be loud everywhere, for receive we want sharpest and most steerable pattern with max. F/B or F/R or F/S in order to improve signal to noise ratio and be able to dig out weak signals from the band QRM and atmospheric noise.

>Furthermore how exactly is F/B ratio specified when ground is involved
>and the main beam is pointing upwards for lets say 30 degree elevation.
>Is it appropriate to get the backward gain also for 30 elevation but

>with 180 degree azimuth difference ?
>

I think, mainly because of the marketing departments of antenna manufacturers, we were presented with the best F/B figure they could find in the pattern. When ground is involved (especially with vertical antennas) it affects the pattern of the antenna, based on the height. I think, now with modeling software, we are best served by exploring the patterns in our particular situation. I think it is impractical to specify the F/B etc. for each height. (We could use say, half or one wavelength height as a practical "standard".) It is possible to have rear lobes at different angles than the front lobe and it would get tedious and have some kind of standard to "standardize" this. We are dealing with three dimensional "animals" and we are best served by observing the 3D patterns in software, which gives us idea what is going on and what to expect in real life (if we don't connect the feedline or involve tower, or conductors in the vicinity :-)

>From the theorectics, Front to Rear (F/R) ratio is specified as the
>difference between gain for the main lobe and the gain for the maximum
>lobe in the backward half of the pattern. So for angle-difference from
>90 to 270 degrees to the main beam direction.
>

Makes more sense and it should be specified for particular ground situation and worst (best) angles of the major lobes.

>My next question, should the whole backward half of the 'radiation-
>sphere' be considered or is this restricted to just the horizontal
>plane ?
>

Ideally, I think in addition, the volume contained by the RF in the lobes in the half-spheres would be best representation of the antenna's properties, just horizontal plane is the next best approximation or picture of it.

>Finally how is F/R ratio specified when ground is involved (main-
>beam points upwards) or when a direction, not equal to the main-beam
>direction is considered ?
>

Again, main lobe can have different angle than max rear lobes, the true spec would specify those lobes, which could change with changing antenna's height over real ground.

>I hope someone can give me a more final answer to my uncertainties...
>

Here is the one, I am sure more would be coming :-)

With modeling software we have a tools to look at different designs, try them in different environments and get the IDEA what affects what. There are more, hard to include factors and variables in real life, but this is quantum leap in what we used to have.

Antenna requirements vary with user's needs, contester looks for every bit of dB in gain or suppression in F/R/S, where DXer might be happy with lot less and casual ham or ragchewer with even less.
I typically sacrifice a dB in front lobe for the cleaner pattern and max rejection in F/R/S - where I can "gain" tens of dB in rejection properties and tremendous improvement in signal to noise reception.
So what I would like to see in the specs? Specify the gain for particular height of antenna in dB (@ deg.) of the main lobe and "gain" (@ deg) of the "worst" rear lobe(s).

My switch does not meet Al`s spec. Spacing is only 2 and 3/8 incches. The base is not white, but it is heavy dark gray slate. But the price was only $0.70 (used) at Electronic Parts Outlet in Houston. They don`t have any now. Mine is not for sale.

Electric Wire and Cable in Houston has this kind of stuff. My load center came from there. It was salvaged from a Ward`s store in Monroe, LA according to an identification tag. It and the breakers I installed cost only pennies on the dollar. This assembly has served me faultlessly for 30 years. I did my own house wiring.

There is likely an electrical surplus and salvage store near you, siimilar to Electric Wire and Cable. My compay used to buy tons of electrical equipment from Electric Wire and Cable. Commercially, we liked to save money too. We always had good results.

Best regards, Richard Harrison, KB5WZI

How can this be? The elevation pattern is developed from the
constructive and destructive interferance between the direct and
earth-reflected radiation.

To the rear, there may be less radiation but isn't it affected by the
reflections from earth the same way?

Can you show an example where what you say occurs?

Soitenly!

I have for example vertical 4 Square design which in EZNEC shows the following properties (in 0 - 180 deg vertical plane):

Front lobe at 10 deg 10.32 dBi
Back lobe
at 120 deg -15.5 dBi
dip at 148 deg -22.5 dBi
at 172 deg. -16.6 dBi
sooo, there is one big front lobe with max at 10 deg.
and two back lobes with minimum between them at 148 and peaks at 120 and 172 deg.

I can supply the EZNEC file (against non-disclosure agreement :-)

I would explain that in real life/earth situations we are dealing with reflections and interaction between the elements, ground, etc. Otherwise blame W7EL for the program producing false results :-) If you had just dipole than your assumption is valid, but with multitude of elements "tings change". Add to it Fractals and things really get messy :-)

There are a number of pre-built loops, but none are low cost. You could
probably build your own, and hide it well enough to be stealthy. Arnie
Coro offered to send plans for one by sending him an email for the 3-turn
loop antenna. HIs email address is

Hi Benson,

Yup, should do the job real good if you want to pull down a chimney.
Even at five feet.

A chimney's strength is entirely in the up/down direction, and much
less in the side/side direction. An antenna + mast under wind load is
significantly side/side strength challenging. Guying reduces that
load; but remember, most chimneys fall through roofs, not down them
(the downside to that up/down strength).

I have some of those RS antenna masts and I wouldn't go over
10 feet without guy wires on them. I also agree with the other
fellow who said he wouldn't use their chimney mount, I had one
also and it's not much on strength. The only way to use one of
them is to guy even a 5 ft pipe on that weak of a mount.

Hi Mark,

Nope....I bought a G5RV at a hamfest years ago and after considering the layout of my property and the location of the trees on it, I never bothered to put it up for the following reasons: My property consists of one lot which has my house on it and the adjoing lot which is vacant. Desiring to keep peace with the neighbors, erecting poles or mast antenna supports is not an option.

The only trees on the vacant lot are at the far end and only about 20' high....and a dipole strung to them would have to have an off center feed....or else the feed line length would be excessive and need to be strung over the house. Since the trees at the far end are low, the antenna and feed would be lying on the roof. The loop goes (more or less) around the perimeter of the property, with the house inside the loop at one end. Since the loop can be fed at any point it makes it realatively easy to run a short as possible feed line into the shack. Cound't do that on my property with a G5RV.

Benson,

Here is something you might want to consider. I am in the process of putting a 10 foot aluminum tube and rotator up on a chimney mount. I can not really get a whole lot of separation between the two straps; so, I picked up a universal mast mount at the RS for about $5, and am going to fasten the bottom of the tube to the roof with that, on the downslope side of the chimney. BTW the aluminum will long outlast the RS steel pipe.. I picked up a 1-1/4, 10 foot section at a local hardware store for 19 something.
Before somebody tells me I can't do this, I used to have a pair of stacked 7 element 2 meter beams on the same chimney. Lasted until the elements started to fall off. Probable be a good idea to run a ground wire up to the mast.

One mistake I made when I first installed mine was using a 4:1 voltage balun (528' #10 THHN wire). It worked fine, and I was happy, although SWR wasn't the best. Somewhere I read that big loops had higher impedance. I then took out the balun, and whammo!! SWR dropped significantly. Anyway.. maybe use a choke balun if you feel the need, but I don't think it matters much. Those Aussies on 40M are Booming in the early morning.

4885. Loaded Log-Periodic Array for HF

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-17 18:51:34 UTC
From: "Albert P. Belle Isle" <belleisl@CerberusSystems.com>
Message-ID: <f3suvu8pm615kot5gjjvrgml2pdf1iclle@4ax.com>
Source record: 128924

Does anyone know of an HF log-periodic that goes down at least as far as 10MHz and uses loaded, shortened dipole elements to reduce the otherwise half-of-the-largest-wavelength-sized physical dimensions?

Has anyone ever used one?

If not, has anyone made and tried such a home-brew?

(My interest is in receive-only for digital utility signals, so efficiency and power-handling are irrelevant to me. I want spatial gain/directivity, but have plenty of Rx sensitivity.)

Thanks.

Good listening,
Al

Hi Brian

I have the HF9VX, the X means eXtra 160 meter coil included in the price.

By the way, you DON'T want the 160 meter coil, it changes the performance of the whole antenna. And the bandwith on 160 is so narrow, you can't get a sideband word in edgewise.

TTUL - 73+ de Gary - KG&#65533;ZP

4887. New to this: Experimenting with tv antenna construction (Channel specific).

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-17 19:34:21 UTC
From: dgilbert@nascospg.com
Message-ID: <a235b6a6.0212171134.162aa0a1@posting.google.com>
Source record: 128926

I am thinking of making a channel specific beam antenna to pull in a distant station or two. I found a program on the net where you enter the desired frequency in mhz and it tells you the size and spacing of the elements. How much gain would an antenna such as this typically have for say channel 7? I have a roof mounted top of the line Radio shack antenna on a tower and have two stations over 100 miles away that the sudio comes in on sometimes but not the picture. They are channel 7 and 19. I thought of playing around and making a specific antenna to see what it did. Whould there be a problem with making the elements out of 1/2 inch or so emt conduit? I know the weight would be more but this would be easire to find. I can weld to if I need to.

Thanks for any help!

4888. Interference

When I was at Texas A&M in the late 50's, in EE I was taught that if two voltage phasors are added vectorially and the phase angle between them is less than 90 degrees, then constructive interference exists. If the phase angle between them is 90+ to 180 degrees, then destructive interference exists. Is this still taught in the EE curriculum? I think it was taught under a section titled, "Vector analysis of voltages and currents", but I didn't save my textbook.

4890. Stupid antenna question...

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-17 21:46:03 UTC
From: autofuzz@lokmail.net
Message-ID: <af24dd6c.0212171346.4e49b177@posting.google.com>
Source record: 128930
Cross-posted to: rec.radio.amateur.antenna,comp.dsp

first a disclaimer: I dont know anything about antennas and stuff so don't bother with the brick bats.. I'm immune ;-)

ok so what i need to do is make a beamforming circuit, i.e. 4 element array that I want to play around with steering the beam with quite narrow beamwidths (perhaps 4-5 degs).

The problem is that before I get there I need to somehow figure out (without using the beamsteering stuff) what kind of signal chars I get in a particular environment. I plan to hook up a signal generator and spectrum analyzer on two different trolleys and move them around doing some very empirical measurements. I'm targetting the 2.4 and 5.8 Ghz range.

so what I thought of doing was to get a very directional antenna (as low beamwidths i can get) hooked up to the analyzer to sort of simulate how the even lower beamforming circuit might behave.

so here are some questions :
1. is this rational!! i.e. apart from all the complexities of doing digital beamforming, does it even make sense to use this experiment as a 'very very rough' estimate?

2. your off the shelf directional antennas have very large gains (i think the lowest i saw was a planar system with a Beamwidth of 7/7 (AZ/EL) with a 25 db gain) but my target beamformer system would have a gain of around 5dB at worst and 10dB at best. So could I add attenuation to the input of a spectrum analyzer and force it to show me a signal at the simulated (bumped down) gain. (BTW can a agilent E4404b do this?)

Thanks.
Auto.

Hi Cecil,

Yes, you could have been instructed incorrectly. But only if you view
such instruction from a purist's point of view. For engineering,
that instruction was adequate to engineering tasks.

I fully expect you were taught the right way, and then immediately
following that, you were taught the shortcut (obvious in trying to
find demarcations by degrees).

The mother science of RF, Optics, has always had the answer:
"Optics," Miles Klein, John Wiley & Sons,
Chptr. 5.2 "Two-Beam Interference"
page 185 shows illustration for "Intensity Distribution" that you can
do for yourself with simple math:
I = 2 * I1 * (1 + cos(phi2 - phi1 - delta))
ave(I) = 2*I1 for an integral number of waves
where:
I: The intensity over the variation in phase (delta)
I1: The intensity of each, coherent source (being equal)
phi2: source2 phase (fixed over interval of delta)
phi1: source1 phase (fixed over interval of delta)
delta: vary phase to observe full 360ï¿½ interference pattern

This is a simpler formula to report here than the more general one
that allows for two sources of non-equal amplitude. I offer the
citation above so that you can pursue that venue if you wish. Two
copies for around $50 are available at http://www.alibris.com

I remember learning something similar in physics in high school, but it wasn't put quite that way.

If the frequencies of two waves are the same, and the phase angle was between 45 and 135 degrees, constructive interference occurs. If the phase angle was between 0 and 45 or between 135 and 180 degrees, then the interference was destructive. The amount of constructive or destructive interference varied with the phase angle, more constructive the closer to 90 degrees, and more destructive closer to 180 degrees.

Of course, my memory might be off a bit.

i am trying to find a simple reference that will show me that what you are thinking of is not realistic. unfortunately the math just gets too deep too quick, but basically i don't think you will be able to generate a beamwidth of 4-5 degrees with only 4 elements.

on the other hand, making measurements of antenna patterns is not a trivial task. just running a couple antennas around on trolley's leaves too many variables and sources of error. you have to worry about not only the antennas you are using for measurements but also the environment all around you. this is why serious design tests are done in anechoic chambers, and there have been endless discussions on here about how to measure antennas in real world environments. reflections from the ground, buildings, the trolleys themselves, the cables connecting and powering them, etc, etc, etc all enter into the equation, not to mention leakage from cables and equipment cases and interference from other transmitters either intentional or accidental.

Cecil:

Hey, as The Bard once said, "a rose by any other name..."

It makes no difference what the sum is called, as long as you can compute
the vector [phasor] sum.

All that is important is the resultant not what you call it.

By the way, speaking of terminology...

I don't believe that mathematicians actually recognize the term "phasor",
rather it is a new terminology
simply "invented" by some electrical engineer [I forget his name now.] many
years ago who apparently
thought that if complex numbers were renamed, they might be easier to
understand.

Not!

Complex numbers, and their calculus have a long and venerable history going
all the way back
to J. F. Gauss and don't need no modern terminology.

Unless, heh, heh... that is... you have a problem with the term "imaginary"
as opposed to "real"!

Ever design a circuit with an imaginary resistor?

Hi,

I'm getting rather poor signal reliability using an ordinary
telescopic
whip for r/c purposes. I was thinking about going in for something
tuned,
but a full half-wave dipole for example would be far too big and
cumbersome. Does anyone know how I could go about making up my own
ariel specifically for this frequency? I was thinking maybe a 'rubber
duck' or something similar
that's mostly coiled up? Anyway,
something small and compact. Any suggestions please!

Thanks
p.

Auto,

I didn't raally follow all this very well but ....

If the "elements" you're talking about are omnidirectional, then 4 elements
won't get you much of a narrow beam.

If the elements you're talking about are highly directional, then
beamsteering may not be possible with signal processing because the beam
patterns are already narrow. (Adding zeros to zeros still yields zeros).
You would have to mechanically steer them first. If you rotate them

individually, then you can use signal processing to add them in phase. If you have them on a line and rotate the line so they remain aligned, then you don't have to do the signal processing to realign them.

Fred

You should assume that the mast and antenna are trying to lever off the top part of your chimney, above the level where the mast is lashed on. Remember that chimneys are only designed to support themselves. Some are so weak that the brickwork starts to move when you first tighten the antenna lashing.

>An antenna + mast under wind load is
>significantly side/side strength challenging. Guying reduces that
>load; but remember, most chimneys fall through roofs, not down them
>(the downside to that up/down strength).

Chimney-mounted masts seem like a good idea at first, but one of the less attractive features is the possibility of a block of brickwork falling through your bedroom roof.

Hardly necessary - ON4UN's 'Low Band DXing' book gives many example of
vertical arrays with a reasonable low-angle front lobe, but an
embarrassing high-angle backlobe which completely messes up the ability

to reject short-skip signals off the back.

The same problem arises in moonbounce yagi arrays, where the pickup of ground noise occurs across the whole "rear panorama" when the array is pointed above the horizon. Strict front/back ratio can often be misleading, because the reality may be a large rearward lobe with just a small dimple at 180deg.

Some designers quote a more general average "front/rear" ratio, for anything beyond +/-90deg.

>I would explain that in real life/earth situations we are dealing with

More like confronting you with uncomfortable realities.

What is important to this *particular* discussion is the energy. Can the sum of two RF voltages ever fulfill the need for additional energy without constructive interference?

> I don't believe that mathematicians actually recognize the term "phasor",

Vectors can be three-dimensional. Phasors are two-dimensional. Didn't you ever read the book titled, "3-D Vectors in Flatland". :-)

> Ever design a circuit with an imaginary resistor?

Nope, but I've designed a circuit with a lossless resistance. :-)

And it doesn't have to hit ANY antenna to do damage. A friend of mine was in a firetower for the local Country Fire Brigade, he is a radio enthusiast and had a scanner up there with him at the time. Not sure what antenna he had but it was either a discone or a vertical of some sort. it was mounted on a pole fixed to the metal tower leg which was pretty well grounded. Lightning approaching, so he unplugged the rg58 and sat it on the bench. Lightning was a LONG way off and going around him but not long after he spotted the lightning he heard a random ticking noise. Upon investigation he found that a spark was jumping from the centre conductor pin to the "earth" of the connector!! Buildup of static in the air. Thats why you hear lightning arrestors "buzz" when there is a storm around.

Source record: 128945

I agree with "Doc". About a month or so ago I first heard of the
"Snake" antenna via an on air discussion between two hams.

In that qso one ham was adamant that it was a great all band antenna,
not only for recieving but transmitting as well. He gave a detailed
description on how to make one : 136' of any type coax, the inner
conductor and outer braid soldered together at the far end (and then
weather sealed), the outer braid opened (cut) right at the PL259
connector at the rig end. Stretched out in as straight a line as
possible but that wasn't critical could be bent (snaked!) around as
necessary to fit on your property.

I had just aquired a 500' spool of RG8X so I immediately made one and
tried it. It did work OK on recieving on 160, 80 & 40 meters.....but
no better or less noisy than my 40 meter dipole. Wasn't worth a fart
in a windstorm for transmitting. Just my experience.....your milage
may vary......

4907. Why a Light Bulb in Series With an Antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-18 00:56:12 UTC
From: Al <ABurzynski@nojunk.satx.rr.com>
Message-ID: <MIPL9.4988$6H6.209912@twister.austin.rr.com>
Source record: 128946

My Icom 745 transceiver has a separate antenna input for receive only of the 100kHz to 1600kHz range. The antenna input first passes through a light bulb (DS1, not a neon bulb), then the other end of the light bulb connects to two resistors, a 10 ohm to ground and a 47 ohm to a low pass filter. This light bulb and two resistors make up a 20 db attenuator, according to the Icom manual.

I have two questions regarding this attenuator. First why a light bulb? A form of variable resistor? Second, can I remove this circuit and just connect the antenna directly to the low pass filter? My goal is to improve reception in the 200kHz to 500kHz range. Ideally I would place a switch at this location in case the attenuator is really needed for LF or AM-band reception.

Thank you.

Hi Cecil,

I rely on the interference (superposition) of two monochromatic waves with their electric vectors perpendicular to the direction of propagation and a 60 degree relative phase angle in order to power my linear amplifier. In general these days it seems the use of the terms distructive and constructive in connection with interference have fallen out of use - perhaps as misnomers.

"I also agree with the other fellow who said he wouldn't use their chimney mount, I had one also and it's not much on strength."

Instead of those RS chimney mounts, I built a solid wrap-around enclosure of the chimney using two-layers of 3/4 exterior grade plywood. This used the entire chimney structure as a support, not depending on a small amount of steel bracketing ("chinmey mount"). I affixed the mast to the plywood enclosure, using four deep U-bolts. I sat the mast structure onto a 4x4 block with a 1-3/4" dia hole in it, about 1" deep. THis block of wood kept the mast from driving into the roof, as well as holding the bottom of the mast "in place."

Over all cost was about $100 in plywood, 2x4's, screws, and primer paint. If you're interested, I can quick scan a drawing of the structure and send it out.

The light bulb is a fuse and protects the front end of the receiver.

One of the educational channels told of a case where a woman was hit by
lightning out of a clear blue sky. The bolt originated in a cloud miles
away behind a mountain range.

I often hear my ladder-line length selector snap, crackle, and pop a
few seconds before I hear the thunder. That means the main lightning
strike was about a mile away yet caused arcing at my house.

I have a five foot tall live oak tree in my front yard. It was hit by
lightning but not by the main bolt. It has a split in the trunk all the
way to the ground and half of the upper part is dead without leaves.
There was a two foot diameter circle on the ground where the St. Augustine
grass died. I figure any tree that survived a lightning strike doesn't
deserve to be dug up and thrown away just because it is half dead.

Not exactly. I just wondered if they teach stuff like that
anymore in the EE curriculum. You see, we didn't "superpose"
voltages back in the 1950's. :-) We just added them vectorially
and accepted the resulting constructive or destructive interference.

Modern day gurus superpose those waves allegedly without
interference. Times sure change in 50 years.

I wouldn't do it, myself. If the thing comes down, and the feedline or tether wire drapes over power lines, somebody could get electrocuted. You could use non-metallic kite string for your tether. But you're going to need a metallic feedline to the 2 meter antenna on the balloon.

Also, isn't this how Ben Franklin discovered electricity? :-)

>I have two questions regarding this attenuator. First why a light bulb? A
>form of variable resistor?

Probably so. I would guess that it's there as a sort of dynamic limiter, to provide the downstream components (e.g. the 10- and 47-ohm resistors) from stress if the receive-only antenna is subjected to very high levels of RF.

This might occur, for example, if you have a receive-only antenna on this input, and a transmit/receive antenna located somewhere nearby. When you key up your transmitter, the proximity of the receive antenna could result in a lot of power coupling back into the rig. In the absence of the light bulb, almost all of this power would be dissipated in the 10- and 47-ohm resistors and in the LPF, and they might overheat.

Since the light bulb filament has a high temperature coefficient of resistance, the bulb would act as a limiter in these cases. If the receive antenna is hit with a lot of power, most of it will end up being dissipated in the light bulb (since it's apparently the high side of the 20 dB attenuator), the filament will heat up, the resistance will increase, the attenuation ratio will increase, and the power input from the antenna will probably decrease to some extent as well. It's a nice negative-feedback system.

> Second, can I remove this circuit and just
>connect the antenna directly to the low pass filter? My goal is to improve
>reception in the 200kHz to 500kHz range. Ideally I would place a switch at
>this location in case the attenuator is really needed for LF or AM-band
>reception.

You could, I suppose. My guess is that it wouldn't help your reception all that much. As I recall, signal quality in HF and below tends to be limited by atmospheric noise and QRM, rather than by the receiver's own self-noise. If you take out the 20 dB attenuation, you'll boost the signal you want, but you'll also boost the QRM and QRN by the same ratio, and I suspect that you won't hear much more than you do now.

You might also be at risk of having the LPF blown out if you key up
the transmitter when the attenuation switch is set to "bypass".
Unless you're on far better terms than I am with Finagle (and with
Murphy his prophet) I'd advise against it.

[snip]

Back in the "old days", that's the way we all made T/R switches for QSK.

The "light bulb T/R QSK switch" was a widely used technique back when
everyone used separate transmitters and receivers rather than modern solid
state transceivers. It worked really well, especially with vacuum tube
front end
receivers which were robust in the presence of big signals.

The T/R QSK switch was nothing more than an appropriately chosen
incandescant
light bulb.

The bulb was simply connected between the transmitter antenna and the
receiver input, and placed above the operating desk where it could be
seen. On receive the bulb's low resistance allowed the receiver to
get the full antenna signal. When the transmitter is keyed, the bulb lit up
brightly and, because of the high tempco of resistance of tungston, the bulb
rapidly went into a very high resistance state, thus protecting the receiver
input and strongly attenuating the received signal.

A side benefit was that when the bulb illuminated upon key down, the bulb
provided an instataneous "on-air" indication.

The design problem was that one had to choose the proper bulb, dependent
upon the transmit power and the speed of T/R change over desired.

Altogether a very elegant design..

Cam,

On the 4, 8 and 16 foot feedline, is it ok to coil these r do then need to
be in one large loop?

TIA

Cecil:

[snip]
> What is important to this *particular* discussion is the energy. Can the
> sum of two RF voltages ever fulfill the need for additional energy without
> constructive interference?
[snip]

Hmmmm... well.

It seems that you are somewhat confused. :-)

When I check with my basic Physics references I find that voltage *is*
actually energy.

And I find that voltage is not a fundamental unit, and for that matter
neither is energy.

Energy is apparently expressed in terms of units called Joules which are
derived from
the fundamental units of force and distance [Newton-meters].

The units of voltage are indeed expressed in terms of units of energy per
unit of charge.
So there is your answer...

One Volt is exactly one Joule [or one Newton-meter of energy] per Coloumb
[of charge].

Thus, if you *combine* charges together [Heh, heh... is that algebraic
addition? Or is that
vector addition? Or is that phasor addition? I dunno!] you should always
get the total
energy of all the charges as the algebraic sum of the energies of the
individual charges.

No?

What?

4922. Re: Earthing necessary?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-18 02:54:50 UTC
From: Dick Carroll <dixie@townsqr.com>
Message-ID: <atoo1q$lh1$0@208.206.142.79>
Source record: 128961

Both the old Gates rigs I looked in on were pretty rugged and required little except an occasional tube. One was a BC1-J and the other an H, and both ran a pair of 833A's in parallel in the final modulated by another pair using a huge choke for the modulating reactor..

But once one of them tossed a real curve, one that I've never encountered before nor since. The station manager called and said the transmitter was off frequency. That was a problem not seen before, in fact the old rigs were very frequency stable. Sure enough, the frequency meter -normally centered- was on the right peg. A quick look under the hood revealed the exciter/driver tube, a 6146, and all the other small associated tubes on that deck were running red hot, their plates glowing brightly. Checking the 800 volt supply, it pegged the 1KV scale on the Simpson. Hmmm, higher than normal voltage? How could that be?

A quick look at the power supply schematic revealed what HAD to be the problem. The power supply used a dual section pi filter with inductive output. I recalled that an inductive output filter supplies average voltage with better regulation, while a capacitive output filter supplies RMS, or 1.414 times average voltage. There was clearly no other way the voltage could have gotten so high - the output filter choke had to have shorted across it's winding, instead of shorting to ground as almost always happened when one failed. That would convert the supply from an inductive output to capacitive output mode. Installing a spare choke brought everything back to normal, the tubes running normal color and the frequency meter back off the peg to center scale.

That remains as the only time I ever saw a HV filter choke fail in that mode.

I considered that case to be a pretty good testament to the ruggedness of the Gates transmitters. Not every device one encounters would hold up under >40% overvoltage and return to normal operation unscathed after the problem was corrected.

4923. Suppressing RF on the Shield

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-18 03:01:26 UTC
From: Mike <"scifiguy at starband dot net">
Message-ID: <k3ovvu0tkrk0bo5g73s9qh6aphngu0qo2a@4ax.com>
Source record: 128962

I have been trying to find a low cost solution to RF on coax shield. Specifically, I'd like to prevent the shield from looking like a radial at the feedpoint of the antenna. Since I'm using LMR600 (solid core), coiling the coax to make a choke is not an option (too stiff). The cable is also too thick for any but the most expensive (and hard to find) large ferrite beads. Using a huge stack of ferrite cores would work, but the cost adds up fast. Is there any negative effect to simply inserting a ferrite core choke between the coax shield and the radial attachment point? This simple solution is curiously missing from the ARRL Handbook, and I'm not sure why, unless it causes a problem somehow.

Thanks.

Even one ferrite st the antenna would help.

I found that 2 turns was ample. Also, for cheapness
try a TV deflection coil ferrite. Plenty big enough!

Cheers

The boom length for the 10-to-30MHz log-periodics I've seen is less
than the 15-meter span of the 10MHz elements.

That's why I'm interested in loading techinques for reducing the
maximum element span to no longer than the boom-length.

You betcha it'll cause a problem. You'll be inserting an impedance in series with your antenna. Remember, a feedline is two conductors. The shield is one of them.

"Current" or "choke" baluns (common mode chokes) are made by winding *both* conductors of the feedline into a coil or on a ferrite form of some kind, or putting ferrite cores over both conductors. In the case of coax, this means working with the whole cable, not a single conductor of it. The desired differential currents on the inside of the coax aren't affected, but a high impedance is created for the undesired current on the outside of the coax. The method you propose will choke both the desired and undesired currents.

I did it a bit differently -- I used a random length receiving antenna,
placed as far as convenient away from the transmitting antenna, and I put
a light blub between the receiving antenna and the relatively low
impedance input to the receiver. I also hung an NE-2 neon bulb from grid
to ground in the RF amplifier stage of the receiver. Nothing ever cooked
inside the old Hallicrafters S20R when used on 80 or 40 meters. Of course
I was only running about 50 watts to a pair of ARC5 transmitters.

No real problem. I just used a somewhat lower amperage bulb there than the
one used in series with the transmitting antenna. (Didn't have "SWR
meters" back then; one just tuned the padder capacitor in the ARC5 final
amplifor plate circuit, and the L network formed by the internal series
loading inductor and an added external capacitor, for maximum brilliance
of the bulb in series with the transmitting antenna.) I suppose there was

a bit of loss of received signal strength in the light bulb connected in series with the receiver input, but not enough to keep me from hearing and working VKs and ZLs on 80 from Ohio over 50 years ago.

But how did the overvoltage situation manage to shift the transmitter off
frequency? Did it allow a parasitic oscillation at some random frequency?

The loops can be coiled in a corkscrew but keep all parts about six
inches away from every other part. I personally use single loops.

It's worth noting that during the Revolution only about a third of the colonists were actually active in the resistance. The other two thirds were either "timid" Loyalists who would have let George have his way with them or who fled from the conflict to a safe haven in the north. Yet all eventually reaped the benefits of the work of the few.

The reflection model tells us that there is V^2/Z0 joules/sec associated
with a voltage wave. Let's assume that Z0=50 ohms, V1 = 100V at zero deg
and V2 = 100V at zero deg. There is 200 joules/sec in each wave. When
we add the two voltages we get 200V at zero deg and 800 joules/sec. Where
did the extra 400 joules/sec come from?

There's nothing wrong with using a different kind of coax from which
to make a coiled up choke. I use RG-400 teflon for all my chokes.
You might want a second choke 1/4WL from the feedpoint.

I took this to mean a tuner isn't required, but it may help.

What if there aren't any charges, Peter, as in the wave radiating from an antenna? You've read enough to know where the energy is in that, right? Actually, Cecil has a right to complain. It does seem to violate the conservation of energy laws. However, as in the case of the two slit experiment that Richard Clark mentioned, although the intensity of the

light a distance from the slits is proportional to (E1 + E2)^2 there is a reason why conservation of energy isn't violated. Do you know what it is?

Got it. Thanks for the explanation, Roy.

I think what I'll do is use small pieces of RG213 with ferrite beads over them (a size that is easier to obtain), and connect them to the LMR600 with male/female N-connectors. Or, I could do the same with longer pieces of RG213, coiled as a choke balun. To save money, I think I'll use coiled RG213 on the HF feedline, and ferrite beads only on the VHF/UHF feedline.

4939. How do couplers in SWR meters work?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-18 07:08:28 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0212172308.4c10bb08@posting.google.com>
Source record: 128878

Can someone tell me how an SWR meter works? I'm looking at the SWR meter project described at:
http://www.arrl.org/members-only/tis/info/pdf/9702033.pdf

I know that an SWR meter works by detecting the differences between the forward and reflected powers. In this particular circuit, the forward and reflected powers are sent into an LM3914 chip. I am familiar with the functions of the 3914 chip. The forward power becomes a forward voltage that is used as the high reference voltage level. The reflected power becomes a reflected voltage that becomes the signal that the LM3914 chip tests.

The forward power and the reflected power look like they are fed into virtually IDENTICAL circuits. (Notice how both the forward and reflected sides are fed into a Ge diode. And the positive side faces the transmission line for both.) I know that there are couplers in this circuit, but I am having difficulty understanding what's going on. How does this circuit ensure that one part of the circuit responds only to the forward power and that the other part of the circuit only responds to the reflected power?

Cecil:

Perhaps the following [analogy] will help you to understand why your reasoning does
not work out.

Remember from basic Physics that Volts are Joules per Coloumb. Then...

Consider
--
A water pipe filled with flowing water which is "carrying" 200 Joules of energy per liter.
[Electrical analogy is 200 Volts = 200 Joules per Couloumb]

Note: This tells us nothing about the total amount of energy being carried past a given
point per second, i.e. power flow, unless we know how many liters are passing per second.

To make things concrete lets say there are 5 liters per second flowing past a given point
[Electrical analogy is specifying the resistance e.g. like your 50 Ohms.] then the power
flow would be calculated as 200 Joules/liter * 5 liters/second = 1000 Joules per second.
[A power of 1000 Watts]

As that great Texan George Strait sings, "Write this down!"

For some reason which seems "intuitive" to practicioners of "reflection mechanics" let's
now resolve this measure of 200 Joules per liter [arbitrarily?] into two [waves] each
carrying 100 Joules per liter.
[100 Joules per liter + 100 Joules per liter = 200 Joules per liter]

Note: This [arbitrary] resolution tells us nothing about the total amount of energy being
carried past a given point per second i.e. the total power flow.

Perhaps it tells us something about the individual power flows!

Let's see...

To calculate the power in each of the [arbitrary] 100 Joules per liter flows we clearly need
to know the number of liters flowing past the given point in each of the two arbitrary

flows.

Since the individual amounts of flow per second have not been specified, we could make
an arbitrary assignment assumption. [What is the electrical analogy here?]

Lets arbitrarily say that the total of 5 liters per second is split exactly in half between
the two with 2.5 liters per second in each flow. Then the total power can be calculated
as [100 * 2.5 + 100 * 2.5 = 250 + 250 = 500 Joules per second].

Compare to what George Strait told us to write down...

Hmmm... something seems to be wrong here!

Let's try something else... What if the split was say 1 liter per second for one flow and 4 liters per second for the other? Then we would calculate the power flow as
[100 * 1 + 100 * 4 = 500 Joules per second.]

Hmmm... something is still wrong?

Let's make another [arbitrary] resolution of the 200 Joules per liter into say 50 Joules
per liter and 150 Joules per liter and then recompute the individual power flows, say
for 2.5 liters each [50 * 2.5 + 150 * 2.5 = 125 + 375 = 500 Joules per second]

Clearly in any case of [two] individual volume flows which add up to the total flow
we will always get a Power of 500 Watts instead of the actual 1000 Watts when we use the
individual flows to calculate the total power.

But... we know that the total power is actually 1000 Watts!

While using a resolution of the total Joules per liter into two individual flows we
always get 500 Watts...

What was it the Romans or Greeks said, "Reductio in absurdium" or something like that?

Clearly our methods cannot be correct and there must be something wrong with the above
reasoning and/or assumptions.

Is it possible that one cannot calculate the total power correctly from the individual
per liter energy measures?

What?

Where is the falicy?

Thoughts, comments?

Works here too - even a coil laid flat on the ground will kill the
shield currents, as verified by a clip-on RF current probe.

>You might want a second choke 1/4WL from the feedpoint.

The shield currents do have a habit of coming back by induction, farther
away from the antenna base, but they're at a much lower level than you'd
see without the choke at the feedpoint.

Hi Yuri,

thanks a lot for your explanation. I see I was not that wrong at all.

To be more specific...

Last few weeks I added some genetic algorithms to my software to
improve the optimization ability. There is other software available to
use this for Yagi antennas, but I wanted have no limitation on the
type of antenna.

To make this work I need calculable parameters which are important for
the average antenna user. So as a first thought I used Forward-Gain,
F/B-ratio and F/R-ratio (for a user-specified Elev/Azim angle of
interest) as the parameters which say something about how good a
certain antenna performs.

I agree with you that the default F/B ratio does not say much, so one
could use the F/R ratio to specify backward rejection. In the modeling
program I use the difference in Gain between the desired direction and
the gain for the max-lobe in the backward half of the sphere. Or maybe
I should use the average value ?

Now I am wondering if there are more calculable things (beamwidth ?)
to mention which say something about how good a certain antenna
performs....

Arie.

Jason

I find it easiest to think in terms of the forward and reflected waves on the three transmission lines. On the main line we have the a forward wave and a reverse wave which are the fundamental quantities we are trying to measure. (although eventually they are combined and presented as SWR) Each has a voltage component and a current component linked by the characteristic impedance of the line.

The two coupled lines have forward and reflected waves induced in them by the proximity coupling to the main line. Their amplitudes are proportional to the amplitudes of the waves on the main line. (The ration of current to voltage on the coupled lines is determined by the characteristic impedance of the coupled lines which will be higher than the main line because of the smaller conducter dimensions)

An important peculiarity is that the coupled wave proportional to the main forward wave travels in the reverse direction to the main forward wave and like wise for the coupled reverse wave which travels in the opposite direction to the main reverse wave.

If opposite ends of the two coupled lines are terminated by resistors which can be adjusted to the coupled line characteristic impedance and a voltage detector is placed on the other the reverse wave can be nulled out on one and the voltage from the detector is proportional to the forward wave amplitude (on the main line). On the other the forward wave is nulled out and the detector output is proportional to the mainline reverse wave.

Hope this helps

Hi Arie,
Thanks for the explanation and effort to include antenna optimization, this is very important aspect of modeling software. I am missing that from EZNEC. I tried to go between EZNEC and K6STI AO antenna optimizer, but it is awkward, need to translate coordinates.

First I thought that you are concerned about the publishing of specs, let's say, as manufacturer would be concerned. But if you are going after parameters for optimization then I would suggest to have two main goals: one to go after max possible gain, second for maximum "cleanest" pattern - meaning trying to reduce back hemisphere radiation, which should really look for minimizing the volume of the back (or side) lobes. To be able to specify the ratio between two compromises for optimization is desirable.

Typically, antenna optimized for max gain, does not have the cleanest pattern, but I think by having software able to do the fine tuning, we should be able to

come up with best compromise as desired.

Another nice thing to have in the modeling software is the feature to involve terrain (like sloping ground, hills) and various ground zones (like ocean front, sand - salt water).

I did some work back in 70ies (hard) modeling on 2m antenna range and designed some decent antennas using Quad and Yagi element combinations (see http://members.aol.com/ve3bmv/Razors.htm). I found that dual reflectors helped to cleanup the pattern in longer boom antennas. Now I am into vertical arrays for the oceanfront.

I will be glad to work with you on fine tuning the software and to verify thing on 2m test range. I will be setting it up soon and I am looking forward to play with this stuff again. I am also outfitting portable tower/trailer setup so I can go around and check things out.

Thanks for all your efforts!

Hi,

I think your main concern should be signal to noise ratio
and not the sensitivity. What you need is 'quiet' antenna
- not a big one. By the way, I had YB400 and I know
that this radio doesn't handle large signals very well. It
means that big antenna can make reception worse.

Outdoor antenna will certainly reduce noise. You can
further decrease noise by keeping it away from any
metal surfaces (notice that concrete walls have often
steel wire mesh inside). Radioamateurs used to say
that "antennas like to breathe with air" ;-) so give it
as much space as you can.

For minimal noise pickup the antenna should be
mounted horizontally. It is good idea to use steel
whip (for example from mobile CB antenna). Anything
between 1 and 1.5 m would be fine (again: you don't
need big antenna with YB400).
You could mount the whip horizontally and pointing
outside the building. The whip is thin and shouldn't
be very visible from ground level.

Next step is impedance transformer. Buy toroid
core FT82-77 and wind 12 turns and 4 turns of
insulated wire (2 completely _separate_ windings).
Connect the first winding (12 turns) between the
whip and ground (you can use 1...2 m of loose
hanging wire as 'ground'). Connect second winding
(4 turns) to coax (do NOT connect coax shield with
antenna ground!). Notice that the main advantage
of using the transformer here is not boosting the signal
(though it does this too) but decoupling common mode
currents. That's why the transformer must have two
separate windings! (Separate windings will also
protect your receiver against statics.)

When you're using the transformer, you should
mount the antenna using wooden supports. Any metal
touching the antenna (for example balcony railing)
- even antenna's ground - may introduce noise (this
is very true in high-rise buildings).

Good luck,
Piotr

"The power supply used a dual section pi filter with inductive output."

Make that a "choke input filter". The charge of the input capacitor to the peak value of the input voltage is the source of the high input voltage. With an input choke in place, the input capacitor isn`t exposed to the peak voltage of the a-c waveform..

I can attest to that. When fooling around with 75 meter antennas, I was transmitting 100? W into a vertical loop, and measured the power being picked up by a dipole that was about 20 feet away. Would you believe 10 W ! I haven't done this yet, but plan to measure the pickup of signals on stacked beams. I suspect the worst case might be some of these multiband beams that use separate feedlines for different bands.

David, ex-W8EZE wrote:
"But, how did the overvoltage situation manage to shift the transmitter off frequency?"

I wasn`t there, but I worked with a Gates 5-A, 892-R final, 891-R`s modulators, for 10 years.
It had a very simple oscillator using a crystal in an oven you could see through a glass window. You could read the oven thermometer.

Frequency stayed within a couple of cycles according to the GR frequency monitor.

Changing the plate voltage by 40% would have
surely thrown the oscillator way off-frequency and pegged the monitor, even if no plates turned red. Oscillators are dependent on stable plate voltage. Raising the plate voltages increases crystal drive. It heats and the resonant frequency changes. It could even break, were it a high frequency crystal.

Best regards, Richard Harrison, KB5WZI

This one is very easy to understand. The two pickups on the stripline
are arranged in opposite directions. Each pickup has a 50 ohm load on
one end and a diode on the other end. The 50 ohm load dissipates the
coupled wave in one direction and the diode rectifies the coupled wave
in the other direction. Each pickup is designed to respond to a wave
traveling in only one direction. The forward sampled voltage is rectified
and the reflected sampled voltage is rectified before being presented to
the LM3914 chip, i.e. the LM3914 is working only with DC values.

I am thinking about building a beam antenna as an experiment for channel 25. (542 mhz). Is it better to put the elements on top of a wood boom with a staple or through? My only thought was they may be more in line on top of the boom in case I did not get all the holes in the boom exactly square if I did it the other way.

Can't let you get away with that one, Peter. Halving the number of joules per liter is a violation of the boundary conditions. You would have to bring additional neutral fluid in to dilute the existing fluid. This is exactly the mistake that Dr. Best makes. You don't realize that you *must* introduce more fluid in order to dilute the original. Dr. Best doesn't realize that he *must* introduce more energy in order to support the constructive interference involved in his voltage waves. That energy is re-reflected energy as can be seen on my web page.

If you don't introduce any more liquid you simply divide the original wave into two waves of 2.5 liters/sec with each liter containing 200 joules.

2.5 * 200 = 500 watts. Two of them equal 1000 watts.

Dr. Best has failed to demonstrate how to take two phase-locked IC-706's, each outputting their maximum 100 watts into 50 ohm transmission lines, i.e. V=70.7V at I=1.414A, and superpose those two and only two waves to obtain 141.4V at 2.828A for a total of 400 watts. Maybe you can show us how to do that, Peter?

CAM wrote:
"I have a five foot tall live oak tree in my front yard. It was hit by lightning but not by the main bolt."

Cecil must have a lightning magnet nearby to draw lightning to such a low target, or is it the tallest thing in the area?

I was in the Muir Woods, north of San Francisco, last month. There are 200 foot tall conifers there which are 2000 and 3000 years old. Nearly every one of them has a wide and deep carbon valley up and down its trunk from lightning strikes. Some think these trees have a right to live also. Others say that we need the lumber, cut them down.

Working in radio stations, I`ve often heard the staccato of flashes across guy wire insulators in advance of approaching thunder storms. Neither these flashes or direct hits aplenty ever did damage to one of these stations. It barely interrupted service when the station was directly struck.

[snip]

Nope, you are dead WRONG here Cecil.

The valance electron cloud in a metallic conductor is, just like the water
in a water pipe,
is completely incompressible. e.g. the number of available charge carriers
in the transmission
system is fixed and additional quantities cannot be introduced.

[cfr Avogadro et al.]

And so... you simply cannot introduce more fluid, e.g. you cannot add any
more electrons
into the complete circuit, unless you change the physical size [i.e. number
of moles of conductor
materail] of the complete closed circuit while it is in operation.

To do this would entail at least one pliers/cutter or soldering iron
operation.

That simply just does not happen in what you have been discussing.

Try again OM!

you don;t say whether this is a wideband antenna or a single freq situation. baluns would help in either case. i've used ferrite beads (over RG-58) to some satisfaction at 220mHz but the best isolation was obtained using a Pawsey stub. I connected a 1/4 wave piece of RG-58 from the center lead at the antenna and soldered the other end of the 1/4 pc to the coax shield, 1/4 wave down from the antenna. Don;t need to use velocity adjustments to the length. Return loss w/o using ferrite beads was about 10 dB, with beads, about 15 dB. Increased to almost 50dB (at antenna resonance) using the Pawsey stub. I used a tracking generator to see the broadband effect of the ferrites and the more narrow-band effect of the isolation stub.

Thanks, Larry. I'll look into Pawsey stubs for my own education.
However, both feedlines will be used for multiple bands. One will be
used for 6/10/15/20/30/40/80 meters (using a coaxial relay to switch
between a 6BTV and a 6 meter antenna). The other will be used for
2/0.7 meters.

It's actually the lowest thing in the yard, lower than my house, lower
than my antennas, lower than the power poles, and lower than the surrounding
trees. Talk about an unlucky tree. Lightning is not perfectly predictable.
I wish I had seen that particular strike. It might have just been a tributary
of the main bolt which might have hit my grounded Rohn 25G tower.

Hi Al; I posted the following a while back. I think it answers your query and that of Icom's design reason. Jeith, VE3JKC

Occasionally postings occur regarding the use of the external antenna connection on some Icom rigs. In some cases there are indications of front end overload damage due to the receiving antenna being in close proximity with the transmitting antenna. In the February 1988 issue of QST, Icom published a "TECH TALK" addressing this situation along with a simple schematic using two shunt 1N914 diodes along with a series #47 dial lamp to protect the front end. You can find it on page 90 in an article titled "The challenge of low frequency DX'ing". Keith, VE3JKC.

Cecil knows not to believe in magic. It is only a trick.

A-C is not magic. Its effective power reguires the same input and produces the same output as d-c. The prime mover takes the same horsepower and the lights burn as bright from either a-c or d-c.

The peak a-c voltage is 1.414 times rms.
The peak a-c current is 1.414 times rms.
Peak power is peak volts times peak amps. Peak power is twice average power, sometimes incorrectly called rms power, since 1.414 squared is 2.

Average d-c power is volts times amps as there is no difference between average and peak. The a-c power relations above are based on real power, not apparent power.

There is no way to correctly combine volts and amps vectorially or arithmetically to increase power in a system over its input, unless power is accumulated as energy and released in high powered spurts or power which would be broadcast over a large area or in a large volume is instead concentrated to give a higher effective power in a smaller space. Again, no magic, the energy involved remains the same.

It`s nature`s rule that we don`t create or destroy energy. There is no way to add 100W to 100W and get 400W, honestly, in real time, and exerted in the same space.

Best regards, Richard Harrison, KB5WZI

> system is fixed and additional quantities cannot be introduced.

That's exactly what I am saying, Peter. It is Dr. Best who needs to discover that the 50 joules/sec of energy/sec that he creates with his 75W+8.33W=133.33W equation is actually there all the time in the form of re-reflected energy. In his steady-state examples, his source is constant power, constant voltage, and constant current (all average). There just ain't any more power available. Dr. Best must make do with what is already there existing in the transmission line at the time of superposition. There is 50W of reflected power that Dr. Best wants us to ignore so he can claim it is not re-reflected power. 75W+8.33W+50W=133.33W. He admits that 50 joules/sec of energy/sec is reflected power in the two rearward traveling waves whose voltages and currents get canceled.

Dr. Best says : "With any matching device or circuit, a steady-state impedance match occurs through the cancellation of multiple rearward traveling waves at the match point."

These two rearward traveling canceled waves are reflected energy. The direction of their energy flow is reversed through wave cancellation. That makes the associated energy re-reflected energy. Yet Dr. Best turns right around and contradicts himself.

He says: "... the steady-state impedance match does not occur through a total re-reflection of the reflected wave."

One of his statements has to be false. Which one do you think it is? Have you read the wave stuff on my web page?

I realize that discussing reflected power with you is like discussing evolution with a Southern Baptist Preacher. :-)

> sensors know which way the wave is travelling?

I thought I explained that. With one pickup, the forward wave sees a ~50
ohm resistor and is dissipated while the reflected wave sees a diode and
is rectified, filtered, and routed to the LM3914. With the other pickup,
the forward wave sees a diode and is rectified, filtered, and routed to
the LM3914 while the reflected wave sees a ~50 ohm resistor and is dissipated.

But, with the back-to-back diodes, there's greater chance of birdies being generated. A manual (or automatic) coaxial T/R switch would allow for a cleaner rx condition.

So Richard, what do you think about the following quote from Dr. Best's QEX article? "In this case, the forward source power of 92.831 W combines in-phase with the re-reflected power of 0.555 W, resulting in a total forward-traveling power of 107.736 W."

I think the statement should be: The forward source power of 92.831 W combines with the re-reflected power of 14.905 W, resulting in a total forward-traveling power of 107.736 W.

4983. Anyone Recognize this Old Logo?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-18 20:08:07 UTC
From: OC_CAM's Razor <Cecil.A.Moore@ieee.org>
Message-ID: <3E00D5A7.1040002@ieee.org>
Source record: 128822

My 90 year old aunt is in the nursing home to stay. We are selling her house and yesterday I rummaged through a bunch of old memories from my childhood. I found a six-tube AM radio with a sticker on it that read: "Shorty Lambert Radio Service, Amateur Radio Station W5OLV". The hand-written date is 1/18/54. Shorty was my Ham Radio mentor back in the early 50's and administered my Conditional Class exam in 1952. That radio brought tears to my eyes.

The radio does not have a brand name on it but it has the company logo. Does anyone recognize it and remember the company? The logo is a circle with horizontal wings. Lightning bolts are coming out from the wing tips. Inside the center circle is another lightning bolt slashing across the circle with a script 'E' on one side and a script 'L' on the other side. It is model number 2701. Help?

North Shore Towers? Lots of high power paging transmitters, etc. on the roof. Does the co-op provide a community TV antenna connection? That might provide FM signals. Otherwise, experiment with indoor antenna placement.

Sounds like you've got a fairly decent antenna now. If you're not
getting a picture at all, I think you've got a LONG way to go.

What's the terrain like between you and the stations? How high is your
antenna now? If it's only about 30 feet above ground, you might have to
put up a real tower (70 feet or more) in addition to a high gain antenna.
And even then, there's no guarrantee.

The gain of a yagi at a particular frequency, is a function of boom length
(assuming good design). Long booms with lots of elements have lots of
gain.

Hi Dave--

He can do it; in fact he'll get many beams that are that narrow;-) because...

It will be challenging to evade grating lobes with such sparse coverage.

In other words, the sidelobes will be almost identical to the 'main' lobe.

The 4-5 degree beamwidth will happen when the max separation is of order 10
wavelengths.

Is there anyone in the San Diego area (I live in Santee) that can help me with shortwave reception problems? I currently have a Radio shack dx-402 to learn with, and I also have a bearcat bc895xlt scanner. The bearcat scanner is connected to a radio shack discone outdoor antenna in which i get really good reception for my scanner. But my shortwave is a different story, I get alot of interference from a radio station close by (KCBQ) and I would like to use the existing antenna to tap into to recieve shortwave? How can I go about doing this and what can I do about the interference coming from that radio station and my computers I have.

Thx,

Joseph Stahley

> ave(I) = 2*I1 for an integral number of waves
> where:
> I: The intensity over the variation in phase (delta)
> I1: The intensity of each, coherent source (being equal)
> phi2: source2 phase (fixed over interval of delta)
> phi1: source1 phase (fixed over interval of delta)
> delta: vary phase to observe full 360ï¿½ interference pattern
You have not affirmed this knowledge having been part of your
curriculum (most EE's are required to take Physics which contains this
material). As such I must respond that, yes, your education was shy
of the full topic; or that you fail to recall it. Either way yields
to the conclusion that you inappropriately apply the argument of
conservation of energy. I have pointed this out in more than one
example, drawn from your own material, to no obvious response. The
source above is authoritative - you admittedly have none to offer.

Cecil, you cannot name one correspondent here that either understands,
affirms or confirms your understanding in these matters. Wonder why
still?

Henry Kolesnik wrote:
"I think the question is why don`t the sensors pick up both (directions of travel)---."

Wires are waveguides. Wire currents generate waves and vice versa.

A wave traveling on wires will generate a wave on a parallel circuit. If the parallel circuit is terminated in its surge impedance (Zo), a resistance, this induced wave will be absorbed in the resistance (a resistor) and converted to heat.

A wave traveling in the opposite direction can be converted to a reading without interference from the absorbed wave.

Best regards, Richard Harrison, KB5WZI

Does the above source agree with me or not? I have a very hard time trying to understand what you are trying to say, Richard. Could you try to be a little more down to earth and a little less cloud-9ish in what you say? I gather that you agree with me about conservation of energy rather than with 75 joules + 8.33 joules = 133.33 joules.

I'm working on it - stand by. I suspect some are unwilling to step into the whirlwind and others are too busy to bother. I also have a potential article being reviewed by QEX and have been told that revealing the contents of that article in a public forum may cause the editors to reject it for publication in QEX as they prefer original material.

Note that Galileo didn't have much support either.

I hear what you're saying Larry, but I think if you check any Icom radio with the separate receiver antenna input, Icom have stuck with this design. I know my IC-756 has it and I sure don't hear any birdies. I think Yaesu does as well. Keith, VE3JKC.

From: Ron <ronn@iastate.edu>
Message-ID: <Xns92E8B350EFE0ronniastateedu@207.225.159.7>
Source record: 128839

Hi, I'm really new to HAM radio (just got my license a week ago), and this has been an interesting thread. Now, I have a question:

Could we use an antenna switch put in backwards to disconnect the antenna from the transceiver? That is, the "input" end of the switch would be connected to the feed line and one "output" would go to the transceiver and the other would go to ground. Then, when we want to use the antenna, switch it to the transceiver and when we are done, switch it to ground.

Would this mess up the impedence matching? Would it help protect from high static charges? Is there something else that we should consider about this idea?

Thanks,
Ron (KC0OQA)

Hi Cecil,

Your question is pretentious. You are challenging a reputable source
to agree with you and only accepting it if it does? That, buckaroo,
is called shopping for a citation. You've admitted you have no
references for your assertions so your challenges have no weight
behind them. A simple glance at the quote, and a pass through the
math is sufficient proof for the rest of this board, your requirements
exceed your own performance.

I suspect you are dreaming - prove me wrong. At best you mock them as
a quivering crew, without enough courage of your convictions or too
indifferent to stand them as their own. For good reason too.

> I also have a
>potential article being reviewed by QEX and have been told that revealing

And the editors? I spit on them if that is your best excuse.
Publication in a vanity rag hardly rises to the distinction of proof.
This goes on the wall next to the notice of the fractal challenge
results.

>>certain antenna performs.

One more important parameter for antenna optimization is the impedance. I always try to design the antenna with desired properties plus 50 (or 75) ohm impedance in order to avoid the matching device loses.
So the main parameters for optimization should be forward gain, F/R, impedance and choice of their ratio for optimization.

Why? It's a simple yes/no question. I don't have the reference. Does the reference disagree with me or not? If so, please quote the part that says 75 joules plus 8.33 joules equals 133.33 joules.

> I suspect you are dreaming - prove me wrong.

I suspect you agree with me, Richard, from things you have said. You still haven't answered two simple questions. Have you read Dr. Best's QEX article? Have you read my web pages?

> And the editors? I spit on them if that is your best excuse.

Then I guess I better not tell you who they are. :-) Exactly what is it about 75 joules + 8.33 joules not equaling 133.33 joules that you don't understand?

You may be missing a lot. All a 4050 ohm, one wavelength dipole needs for
a perfect match to 50 ohms is 1/4WL of 450 ohm line.

Some old radios had such a scheme. I was on location in a place far south many years ago and had gone to bed when, just before drifting to the land of Nod, the little room where I slept and kept the radio started to blink. Another operator, some distance away, had fired up on CW and my still-connected antenna was picking up enough energy to cause the protection lamp to glow. Mind, was a serious antenna with a saltwater return.
The non-linear properties of a light bulb have been used in oscillators to stabilize their amplitude. The most famous use was by HP in their first product, the HP200 audio oscillator. Look inside and you will see a 7.5 watt light bulb in a porcelain socket.

Heh, heh... hey, only in the steady state! I'm actually on your page for transients!
When energy is surging up and down the line to charge it up, rather than across it.

Aside
--
It's only during the transient regime that energy surges up and down transmission
lines, in the steady state when the line's distributed reactances are fully charged,
all of that stored energy just surges back and forth between the distributed inductance
and capacitance, i.e. is sloshes sort of sidewise on the line rather than lengthwise. And
BTW... all the same formulas and equations apply during both transient and steady
state and at all frequencies all the way down to and including DC steady state.
Pretty simple, needs no hand waving and re-re-re-re *splanations*.
--

And... Hey I'd like to help you to convince Dr. Best, but I can't reallyhelp with your
Steve Best problems... you see, although I like Dr. Best, and I believe, unlike many
Ph.D.'s, he is not over there on the "dark side" asking us to believe just because he
got the Ph.D. and we didn't, but that he's actually "with us".

However in his efforts to impress with his command of mathematical pyrotechnics,
his *splanations* become far too complex for my liking, my eyes go blurry, my mind
goes blank, and I loose him after the first 3 equations, and the first couple of re-re-re
reflections, or so... By that time he could be claiming perpetual motion, I

just wouldn't
know, cuz I'm asleep.

Why Dr. Best, Walter Maxwell, and a few others make such simple things so complicated I'll never understand. I'm sure that no one, except perhaps yourself, has
the time or energy to follow their strained, convoluted, obtuse and obscure arguments.

BTW... are Southern Baptists operating in the steady state or the transient regime?

Happy Holidays,

Yep, but here we are talking about optimization feature for arrays in the software, how much optimization can your one wave dipole take? (Wire diameter, color? :-)

Most widely used impedances of feeder cables are 50 or 75 ohm. This is what I try to achieve with array design. If it is not possible, then of course, matching device should be used to take advantage of antenna properties and effcient power transfer. But in many situations it is possible by little bit more of tweaking to achieve desired impedance as well as other good properties.

There's a really neat reference on the web at:

http://www.ardman.net/

Click on the "Free TV Coverage Maps" scrolling banner at the top of the
page, then enter your zipcode (or latitude/longitude) and press the
"Submit Query" button. It will return the distance, bearing, estimated
field strength, and signal grade for every station within a given radius
of your location.

I was curious about their exact area of disagreement and the subsequent
resulting political power structure. I'm probably not the first engineer
to take a close look at an impedance discontinuity, but I am not aware
of any references on this exact subject. Of course, I don't have access
to a lot of references.

Does your reference indicate what happens in the non-glare
coating on picture glass? If so, exactly the same thing
happens at a matched impedance discontinuity. Wave cancellation
of two reflected waves happens. The only question is: Where does
the energy in the canceled waves go? I have presented a multiple
choice question that nobody has answered:

When two waves, traveling in the same direction in a transmission
line, cancel, the energy in those two waves:
1. Keeps going the same direction
2. Reverses direction
3. Stands still and accumulates
4. Disappears from the system
5. Other, please explain _____

Seriously, in this example, the light hitting the non-glare glass ALL (*)
goes through the glass - none is reflected. Cancelled waves is another way
of saying, "Do not enter in the first place."

(*) Of course, the non-glare coating (and even the glass itself) won't be
100% transparent so there will be some efficiency factor - but that is a
side issue and shouldn't be allowed to distract from the main topic.

Peter, K1PO wrote:
"---it does not tell how or why it works!"

Sorry I was unclear. I`ll try again.

A directional coupler commonly used for SWR, works by sending samples of one direction to the trash bin of conversion to heat. A sample of the wave traveling in the opposite direction encounters a termination which does more than convert all the energy traveling in its direction to heat. Some of the energy is used to power an amplitude indication. It is not perturbed by energy traveling in the opposite direction as this is being convertd to heat.

To sample the opposite direction of travel, the the dummy termination load end and the indicator end of the sample line are traded end for end. Another way to do the same job is to use separate sampling lines for the two directions of travel. Where one line has its sample sensor, the other line has its dummy load and vice versa.

The samples obtained of the energy traveling in each direction allow determination of reflection coefficient and SWR that the line might have were it long enough and efficient.

Best regards, Richard Harrison, KB5WZI

How do the couplers work?

The coupler consists of a piece of transmission line with the outer shield removed running from the input jack to the output jack with some form of conductor coupled closely to the transmission line to act as a pickup. The pickup device is either a toroid with several turns of wire around it slid over the transmission line, or, a piece of wire -- usually heavy gauge -- running parallel to the transmission line inside the meter.

As the RF from the transmitter travels along the transmission line to the antenna, an magnetic field is set up around the transmission line -- remember, RF is AC and alternating current passing through a conductor causes a magnetic field to form around the conductor.

As the magnetic field rises and collapses, it passes through the pickup device, which is itself a conductor. As a magnetic field cuts through a conductor, it induces an AC current in the conductor -- in this case, the pickup device.

A diode runs from each end of the device -- this diode rectifies the AC into DC and connects the DC current to a measuring circuit.

Power running from the transmitter to the antenna causes current to flow in one direction, power running from the antenna to the transmitter causes current to flow in the other direction. The diodes pick up the voltage in the two directions and pass that current to the measuring circuit where you select whether to measure forward power or reflected power.

We know there are reflections from the surface of the film and from the
surface of the glass, i.e. two sets of reflections that cancel. So if
none is reflected, then all must be re-reflected.

There are numerous 'Theories of Light' - none should be taken too seriously. It's all 'Superstrings' after all (maybe).

An old example of how to approach The Whole Damn Thing...

Q: Is light made of photons or waves ?

A: Light is light. God/Nature made light. Light will do whatever the hell light wants to do. Man invented the concepts of rays, and waves, and photons and so forth. They even hand out prizes for these inventions. Often light will act in a way that can be explained by use of these man-made models. When the models fall apart, someone will invent a new model and win a prize.

Honestly, I don't believe that non-glare coating on glass led to any theoretical revolutions in the field of physics (optics). I remember doing those physics exercises (non-glare glass - wave cancellation) in High School Physics (perhaps repeated in University Physics 101). I'm pretty sure that the explanation was that wave cancellation is like a 'dead short' (in that direction) and that prevented the energy from going that way (being reflected).

It is certainly a mistake to consider the two partial reflections (of non-glare glass) in isolation from each other - they're only a quarter lambda apart and the photons (excuse the mental shift) certainly don't treat the two reflective surfaces in isolation from each other.

If you really do see a problem with non-glare glass (and you're not just being rhetorical), then you need to fill that gap. I don't believe that there is a Noble Prize waiting in 'The Non-Glare Glass Problem'.

A little over 40 years ago one afternoon I wondered about this. I took a pencil and a piece of paper and thought about the mutual inductance between the pickup wire (sample wire) and the centre conductor of the coax, the capacitance between these two things, and the termination resistor at one end of the pickup wire. I wrote down a few equations involving things like Ohm's law and its variants for inductors and capacitors and Kirchhoff's two laws, and I did a little algebra. Five minutes later I knew how "SWR meters" work.

The final equations bore a strange resemblance to those involved in Wheatstone bridges (he says with a grin).

I should have been working on my math dissertation instead of doing undergraduate EE stuff covered no doubt in courses I had never taken, and the immanent arrival of daughter Susan, then about -4 months old, encouraged me to get back to the dissertation. It got finished about 2 months before Susan was born.

Paper and pencil are still available. E = IR, E = L*dI/dt = L*d^2Q/dt^2, and E = Q/C, along with the Khirchoff Laws, are all you need. The solution is left to the reader ;-).

If you do a Google search of the archive of this group, you'll find some really good explanations about how directional couplers work. I wrote one or two that people years later told me were useful to them, but I know that others may well have explained them better, too. As others in this thread have said, it's that the difference between forward and reverse power is the direction of the current for a given voltage. For each wave, the voltage and current are related by v=Zo*i.

Cheers,
Tom

Yuri,

The latest version 5.0 version of the software just contains an AO
alike optimizer. During last few weeks (in my sparse free time) I
added a number of Genetic Algorithms for single-freq or freq-sweep
optimization The new subroutines work surpisingly well, but I am not
very satisfied about what antenna characteristics one would like to
have for optimization.

In the latest version this was any combination of Gain, F/B, F/R,
R-in, X-in and efficiency with user-selectable weighting factors and
target values, but maybe other characteristics are preferable.

Anybody with suggestions (and how you would like to have them
calculated)...?

Arie.

Check your answers at "An Inside Picture of Directional Wattmeters; What
They Do and How They Do It" by Warren Bruene, (then) W0TTK, in QST for
April 1959. It's a beautifully clear explanation, and a classic article.
I wrote a two-page summary in my magazine column for September 2001, but
unfortunately neither of these references is available on the web -
one's too old and the other's too recent.

All of these SWR sensors work by taking samples of the current in the
line and of the voltage between the line and the shield. When you
reverse the sensor in the line, the current sample reverses its phase
but the voltage sample doesn't... and that's how the bridge gets its
directional properties.

The similarity to a Wheatstone impedance bridge (as used in SWR
analysers) is no coincidence. If you wish, you can re-draw the bridge as
a series resistor sampling current, and the other two fixed resistors
forming a voltage divider; and then you can analyse it by Bruene's
method.

On the other hand, you can think of an SWR meter as a kind of impedance
bridge and analyse it in those terms, without ever mentioning the words

"wave", "forward" or "reflected".

Both approaches are equally valid, and there is no conflict between them.

David:

[snip]
> The final equations bore a strange resemblance to those involved in
> Wheatstone bridges (he says with a grin).
:
:
> David, ex-W8EZE
[snip]

Interesting! (He remarks with his own grin.)

Certainly mathematical expressions for the output voltage of the Wheatstone bridge
[open circuit voltage across the bridge arm] look like the mathematical definition
of a so-called "reflected voltage", usually symbolized as "B" and calculated by the
bridge [essentially the bridge is an analog computer] as B = V - RI where
V and I are the respective voltage and current at a single point/plane on a transmission
line or network of characteristic impedance R.

But displaying that equation doesn't physically explain how the heck Wheatstone bridges
sort out the direction of travel of waves and/or the values of their minimum and maximum
voltages and currents [for SWR purposes] as observed at points spaced out along a legnth
of at least a half wave length by simply forming an output based upon observations of the
voltage and current at a single point/plane in the system?

And further, not all SWR meters make use of such single observation point bridges.
Some make use of distributed structures, e.g. slotted lines, and parallel waveguides.

What exactly is the mechanism by which such devices detect directionality?

I know all of the mathematics, I'm looking for a physical explanation, not a display of
mathematical equations. Give me something like the Doppler effect which is used
to tell if an object is approaching or receeding from the observer, etc...

What?

[snip]

So this must mean that some of the charges/Couloumbs [as represented by
electrons I presume]
are moving in one direction, say to the left, while others, are
simultaneously moving to the right.

Can this true?

I was always taught that like charges attract and unlike charges repel,
positive charges always
tend to move from positive to negative potentials and negative charges
always tend to move
from negative to positive potentials and so *all* of the charges of the
same kind, clearly
these are electrons in RG-58, must all be moving in more or less the same
direction. What?

Heh, heh...

I can just see two electrons passing each other going in opposite
directions, one says to the other,
"Where the heck do you think you are going? The positive direction is down
this way, you'r not
going in the *positive* direction, get with the program!"

I often ask myself, "If I were an electron, which way would I be going now,
and why?"

Thoughts, comments?

Peter, K1PO wrote:
"---these are electrons in RG-58, must be moving in more or less the same direction."

You may recall the tube packed with balls analogy. Tap the balls from one end and all are displaced in one direction. Tap the balls from the other end and all are displaced in the opposite direction.

Repeat the sequence as often as desired. Individual balls don`t migrate through the tube. They just slightly move back and forth, but their energy travels end-to-end.

Electrons oscillate in accord with their excitation in conductors and are not required to migrate through its length to relay energy via the conductor.

Peter also wrote:
"I can just see these electrons passing each other---."

This isn`t needed for bi-directional simultaneous energy transmission. In fact, the electrons are superfluous, but impose conditions on transmission. Energy radiates through vacuua where there are few if any electrons. It is energy which moves at speeds approaching that of light, not the electrons, which have the inertia of their mass.

Source record: 128774

Hi,
Anyone got any ideas on a phase detector for a remote automatic antenna tuner I am thinking of building. The tuner portion wil consist of motor driven variable inductor and capacitor in a switchable "L" network. The rf for the tuning process will be supplied from an MFJ-259B back at the operating position.
I measured the output of the mfj into 50 ohms and got 1 volt rms at 20 ma. I am afraid this is not enough for a standard diode phase detector even using germaniums. I suppose I could use zero bias Schottky diodes, but don't have any at the moment and don't know where to get them. Also need ideas on ratio detector so the tuner knows the voltage and current ratio is 50 ohms.
Also the only time rf will be present in the phase detector is during "tune". otherwise the detector circuits will be bypassed. I plan on running a kilowatt from time to time and don't want to fry the detectors.
Thanks for any ideas.

As described in earlier postings, a traveling wave moves in a particular direction. Coupled into an external circuit, it is configured to induce a traveling wave in a particular direction in the coupled circuit. The "mechanism" is whether the induced wave is trashed or measured.

A refinement of the Bird wattmeter is use of an "earmark" of a once-reflected wave. One or more odd-numbered reflections leaves a wave with its volts and amps 180-degrees out-of-phase. Bird cleverly adjusts samples of volts and amps to be exactly equal in producing indicator deflection.

So, in the Bird, the incident wave sample deflection is exactly twice the magnitude that either volts or amps produces alone.

In the Bird, deflection produced from the reflected wave under the above conditions, is exactly zero as the out-of-phase volt and amp samples exactly cancel.

Nothing is perfect, but the Bird is good enough for most practical purposes.

>have for optimization.
>

I better try it. I am looking forward to "play" with it.

Again, for this demanding user, I am looking for the transmit antenna to have maximum gain and efficiency, so I can lay the loudest signal in particular area. F/R is not of big concern, it might be even desirable to keep the QRMers away. Minimum power loses in the cable and any matching devices. Then again, trying to include the feedpoint impedance choice in order to avoid matching devices. So here we are shooting for max forward gain, efficiency and desired impedance.

For the receive antennas, I am looking for cleanest pattern with minimum rear/side lobes. This minimizes the atmospheric QRN pickup, band QRM pickup and this can contribute tens of dB to noise and unwated signals rejection (which can be traded for fractions of dB in loss of forward gain).
With tunable antennas (like Step-IR) this is quite feasible to implement into the antenna (array) design and make it T/R switchable.
Here we are shooting for cleanest, one lobe pattern.

When designing Razors on 2m test range, I found that if I optimized the antenna for particular height and then changed the height, by reshuffling the elements I would improve the performance. So the conclusion was: antenna array should be optimized for the height and ground quality it will be implemented in. This is why inclusion of terrain and ground conditions (sloping hill, sand/salt water front) will be also very helpful.
This would for example show, why I had problems with 1600 ft beverages going down on sloping hill (they were "deaf") before I put them up. When I cut them in half, they were OK.

Another factor is antenna structures (towers, guy wires) and other hard to model stuff (houses, electrical wiring, etc.) within couple wavelengths that contribute to distortion or enhancement of the array performance.
Are we going too far? :-)(

I didn't have the chance to use 4NEC2, I hope to do that soon, I wonder if others have used it and their comments. Is there coordinates "translation" tool for dimensions between various programs? That would help to compare results and fine tune the designs.

Rich, K2CPE wrote:
"He was in Ushuaia, LU8XP."

Thank you for the identification. He wasn`t using my rhombic. YPF, the Argentine Oil Company has facilities which they confiscated from us on the north side of the island.

Ushuaia, when I was there, had only one hotel and it was very primative. It`s a very cold place and the hotel had an enormous pot-bellied stove near the front door.

Ushuaia backs up against a mountain range which cuts off the north side of the island, but Argentine "highway" No. 1 starts right there. Ushuaia has a deep-water port which is denied the north side of the island by tides which normally exceed 30-feet. When the tide goes out up there, it`s more than a mile from where the shore was to where the shore now is. The "highway" connecting Ushuaia with the north is incredibly precarious. We tried using Ushuaia`s port one time, then it was back to landing craft and barges to ferry goods between ships far out at sea and the shore. We had to put our oil loading terminal far out in the sea to ship out our production. Daily hurricane winds made that operation fun too. A deep-water port at Ushuaia wasn`t of much help then, but an oil pipeline could have made it useful to ship out the oil from the north. We didn`t have time to build a pipeline, but maybe YPF has.

Best regards, Richard Harrison, KB5WZI

The voltage and current are in phase for forward energy. The voltage
and current are 180 degrees out of phase for reflected energy. Assume
that's all you know and invent your own method of detection. Chances
are, it won't be an original design.

The waves in water are not the water molecules. The waves in the free electrons in a wire are not the electrons. The waves in both instances are the energy, not the particles.

If I put a steel bar to your head and hit it with a hammer, do you really think a steel molecule has moved from one end of the bar to the other?

If you anchor a rope at one end and then pop the other end, is the wave moving down the rope causing rope molecules to move from one end of the rope to the other?

> I often ask myself, "If I were an electron, which way would I be going now,
> and why?"

Electrons in a wire move in the direction set by the total emf which is either positive, negative, or zero, but they certainly don't move at the speed of light. We are discussing wave energy not physical movement of electrons. Just as water molecules carry wave energy without moving very much, electrons carry wave energy without moving very much.

Which way would you move? Knowing how ornery you are, you would probably choose a fractal pattern of movement. :-)

> grips on their arguments.

Amazingly enough, Dr. Best and Mr. Maxwell are apparently making the same conceptual mistake. Here's the mistaken concept as I understand it.

"The only reflected energy in the entire transmission line is the energy reflected from the load."

However, there is lots of reflected energy at the match point. Dr. Best apparently doesn't realize it, but "rearward traveling waves 1 and 2" in his article are reflected waves. When they cancel, their combined energy reverses direction and becomes re-reflected energy which Dr. Best needs for his superposition (constructive interference), but he continues to assert that it doesn't exist.

IMO, Dr. Best and Mr. Maxwell are about two inches apart in their arguments but neither side will budge that last inch. :-) My goal was to bridge the gap in their arguments and I believe I have done that although I may not have explained it very well.

[snip]

Heh, heh... Me? Ornery? :-) Hey I never said electrons move at the speed
of light!

You are putting words in my mouth. Where or when did I ever say that?

Heh, heh...

As my favorite President used to say, "There you go again."

Attempting to change the subject to avoid the issue. Well Cec that just
won't work!

As I am sure you know, electrons move at the drift velocity which is
substantially
less than the speed of light.

This is analogous to the speed of the water molecules in a water pipe
[slow], and the
energy transmitted by those water molecules [fast]. The energy always moves
a hell of
a lot faster than the drift velocity of the particles that "carry" it.

The "energy" being transmitted by the slowly moving electrons in a metallic
conductor
often moves at close to the speed of light, but the electrons themselves
often move
at only a few meters per second. [It all depends on the density of the free
electrons.
You have to understand moles, molar measures, Avagodadro's Number and the
metal's density to compute the actual density of free electrons and their
velocity

given the value of the current.] But then Cecil I know that you already knew
all of that, and... BTW...

What the hell does the electron velocity have to do with this discussion anyway?

It was/is the electron's *direction* that we were discussing not their speed!

Jeeesh! ;-)

Happy Holidays,

How can you decide direction without also deciding speed?
Going north or south at zero speed is the same thing.

Gary, I have done extensive testing lately regarding phase detectors for my auto-tuning minibeam project. I tried diode DBMs, active DBMs, XOR type detectors, etc. There is only one device I tried that I think would work in your case...an Analog Devices AD8302. Below are details...

In my case I needed something that would continuously monitor phase and element currents in my beam while transmitting...even in SSB...necessitating a dynamic range of over 60 db with minimal phase variation. The design I finalized uses several chips from Analog Devices. For the limiting amps I use AD606's, which also give me a signal strength output that I use for monitoring current levels, followed by an AD8302 phase/level detector chip. This is designed for remote monitoring of performance in cellular systems. It is a great chip, but very difficult to deal with as it is a TSSOP package. They offer a prototype board for $100 though. It has ~60 db gain, so should work with low levels. Even though the AD8302 by itself would theoretically have worked, I got phase variation of over 10 degrees without the log amps. The phase detectors used by tuner makers like SGC are typically far worse than this, however. I also tried using the log amps followed by monlithic amps and a diode DBM...you may find this acceptable, but in my case there were a number of problems with this design.

I use a serial interface with A/D converters and relay drivers, along with a software control panel, to sample the parameters for the phase detector and auto-adjust the DE tuning box which consists of stepped coils and caps in a L-network arrangement...and also adjust the tuning of the reflector for optimum performance.

I am in the process of documenting the project and will be submitting an article to QST for publication. For more info, see my website under LP-Autobeam near the bottom of the page.

Hey don't you remember your calculus and the theory of limits?

It all depends upon from which speed you approach stationarity.

If you approach zero speed from a positive speed, in the limit you get zero speed.

If you approach zero speed from a negative speed, in the limit you get zilch speed.

North and South have nothing to do with it because its a guided system.

Just a point of clarification:

I have never said that you could do what Cecil is suggesting above - i.e. take two separate sources and combine them such that they deliver more total power than the sum of the power being delivered by each. Superposition principles can be simply applied to the voltages and currents in this system to demonstrate that this is not possible.

Come guys, it's not what you say it's how you say it...
Your face could stop a clock... We know what that means but it's not nice!
Time stands still when I see you. Not as direct but we get the meaning!

Another axiom: If you can't explain something to others so that most of them can understand you probably don't understand if yourself!

So lets see if I meet line!

Since I've gotten older (62) I don't remember some things as well and to refresh my memory I got a copy of Bruene's 59 QST article and re-read parts Walt Maxwell's book Reflections.

The question was, how does a sensor for an SWR meter work as it seems like the diodes aren't smart enough to know forward from reverse! Walt explains that in the forward wave the voltage and current are in phase. However when a wave is reflected, the current is 180 degrees out of phase, (page 3-6 or 3-7 depending on issue) and that is because the current has changed direction to come back to its source. Bruene goes a little further saying that voltage and current on a line can be considered to have 2 components, a forward and reverse and explains that with phasor diagrams. So remember that current is moving forward to the load and any mismatch causes a reflected current coming back to the source. The returning current is 180 degrees out of phase (as it must be) and is real true power in that it can be used to heat a resistor. Walt points out that some writers have furthered the misunderstanding of reflected power by saying that is not real power because they have incorrectly assumed that the current is 90 degrees out of phase. And if you recall P=ExI for DC and P=ExIx cos. (phase angle), the cosine of 90 is zero but the cos. of 180 is ONE.

OK, now lets put a leg of the transmission line thru a few of turns of wire (transformer) and connect each end to the cathode of a diode, each diode going to a microammeter that is grounded. We also need a dc ground return for the transformer so lets connect a 100 ohm resistor to each end of the transformer.

Now here comes that part that should explain what happens. The forward current will induce a current in the transformer according to the right hand rule and only one of the diodes will conduct giving us a relative indication of the forward current. The other diode can't conduct from the forward current because it's biased off. But as soon as there's reflected current it will turn on, start conducting and send a relative amount of current to the other meter while the other diode is biased off.. I've left out the capacitors and rf chokes for simplification. This is hard to do without a blackboard but lets see if this helps.

Hey Tom:

[snip]
"Tom Bruhns" <k7itm@aol.com> wrote in message
news:3200347.0212191040.43f7509b@posting.google.com...
> Soooo, Pete, do you believe the transmission line is a linear system
[snip]

Yep, the transmission line, the one we are all discussing, is a linear
system.

And furthermore all of the accompanying force fields are considered to be
conservative.

The mathematics is all very clear, at least to me, heh, heh...

Here, I'll recap.
--
The "voltage wave" variables are labeled A and B, the "circuit" variables
are labeled V [Volts] and I [Amps]. Of course one could work with
current wave variables or even normalized dimensionless wave variables,
but it really doesn't matter since, mathematically at least, the wave
variables
are nothing more than simple linear combinations of the electrical
variables.

The "reflected voltage wave" at the plane in question is: B = V - RI
and the "forward voltage wave" at the plane in question is: A = V + RI.

In matrix notation: Waves = [Matrix] x Electricals, where matrix is:

|1 -R |
|1 +R|

The "waves" are simply related by the linear reflection coefficient rho.

rho = B/A = (V - RI)/(V + RI)

The VSWR, and the ISWR since the system is linear, would indicate
the ratio of the largest to the smallest voltage on the media if the media
had any length, but it also holds for an infinitesimal lenght and is defined
in terms of rho as:

VSWR = (1 + |rho|)/(1 - |rho|)

Where V is the voltage across the reference plane, independent of the
path taken in the evaluation of the line integral which defines V, and I is

the current flowing in the positive direction perpendicular to the plane.
R is a function of the reference media and because of linearity this
reference impedance [characteristic impedance] is equal to the
ratio of voltage to current in that media, R=V/I.

The so-called SWR meter is just an analog computer which measures
V and I and then computes B = V - RI to give an indication of reflected
voltage [cfr. Reg Edwards TLI!]. To make the mathematical division
operation simple, most simple VSWR meters then force or assume
a nominal unit value for the forward "wave" i.e. letting, A = 1.0, or else
they utilize a nomographic analog divider [crossed needles indicating
A and B on separate meter needles] thus providing an indication of
VSWR.

And so... in simple terms, a VSWR meter is an analog computer with
analog sensors which measure V and I at a point/plane and then compute
VSWR according to the above mathematics for display.

Such a meter if it DC coupld and is well designed can provide an
appropriate indication over all frequency ranges down to and including
DC, whether or not there is an actual transmission line present, or whether
or not, say in the case of DC there is an actual standing wave present.
--
See, I know all that mathematical stuff!

But wow... all that being said, I understand the mathematics, but I still
don't understand in a physical sense how the sensor detects which
direction a wave is going! What the OP wanted was a simple
physical explanation. How difficult can it be?

A = V + RI goes one way and B = V -RI goes the other, but...

What the heck are A and B? What are they made of? [Both
volts and amps in linear combination.] What do they look like?
[On a scope they would be voltage sine waves or simple DC
values for DC "waves".]

But that's not satisfying enought for me...

You know, I want a physical explanation, not a mathematical one!

What does the forward wave A actually look like and what does
the reflected wave B actually look like, and how can I tell
one is going West when the other is going East? And are the
electrons in A going in the opposite directions to the ones in B?
Or are all the electrons going the same way in I?

Inquiring minds want to know!

Happy Holidays,

--

5063. Newbie question about antenna materials

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-19 20:33:16 UTC
From: nenlaven@webdreamland.com
Message-ID: <97503afa.0212191233.29006301@posting.google.com>
Source record: 128802

Over the next couple of weeks I am going to try my hand at making a 10m beam antenna. I have all the measurements I need for the length of the elements and the spacing, etc, but I have a few questions about the materials involved and the actual construction.

1 - For wire antennas, do you remove the insulation from the wire or leave it on? From reading on here I am pretty sure it can remain.

2 - Does it make a difference whether the wire is stranded or solid?

3 - I am going to be using treated lumber for the boom and for the supports for the elements. Is it okay for the wire to lay directly on the wood, or should I put in some supports to raise it up above the wood a bit?

Thanks for your time,
Eric

>Gary, I have done extensive testing lately regarding phase detectors

You certainly have Larry, thanks for the info, just what I was looking for.

>There is only one device I tried that I think would work in
>your case...an Analog Devices AD8302.

Looked briefly at the spec sheet for the 8302, looks like it would work quite well except for the $30 price tag and the type package they offer. The evaluation board was $151, both over buget , at least for the moment.
>For the limiting amps I
>use AD606's
These are $50 each. Aren't the limiting amps just to provide zero crossings to the 8302? Do they have to be log amps?

>Even though the AD8302 by itself would
>theoretically have worked, I got phase variation of over 10 degrees without
>the log amps.

How do you get your voltage and current samples? Is the phase variation due to the sampling devices, or do you think it is something in the AD8302?

Visited your website, very informative. Looking forward to QST article, sounds like you have done some nice work. Thanks again for the information.

21Jun2000 UK: Airlines test device to trace mobiles.
By Keith Harper, Transport editor.

Airlines are testing warning devices in their cockpits to locate active mobile phones after tests by the civil aviation authority revealed that mobiles were a threat to the safety of aircraft.

Tests carried out by the CAA on board two aircraft found that phone transmissions produced interference levels which could disrupt aircraft systems.

The tests back up the existing CAA ban on the use of mobile phones on aircraft while the engines are running.
The CAA said last night: `We are not happy with the present state of affairs. Tougher measures are being taken by airlines, but if they do not work, we will have to consider alternatives, including extra shields in the cabin to stop interference in the cockpit.'
The CAA, Britain's regulatory authority for the industry, dismissed suggestions that passengers should be forbidden to take mobiles on board.
`But we have to face the fact that accidents happen and that mobiles which are switched off and stowed in the holds can turn themselves on, and pose a threat to safety.'
The CAA's tests found that interference levels varied with small changes in the location of the telephone and that passengers in the path of the transmission reduced the signal. This meant that the number of passengers could affect the level of interference.

Hi Gary...I guess they have raised their prices a bit. You could play with some cheaper devices, but I didn't have a ton of luck with them. I tried a MC3356 fm subsytem chip which has plenty of limiting, but the output is low...about 100mv as I recall. I followed the chips with MCL SAR-3 monolithic amps to boost the level up to that needed by a diode DBM.

The reason for the log amp/limiters was to provide dynamic range...and to provide a constant level to the DBM. Since you are using a steady signal from the MFJ, you probably don't need a limiter. You might want to look at something like a MC1496 active DBM, which requires a lot less signal than a diode DBM...at least on the signal port. It is still widely available.

I use toroid current sampling at the elements...it is nonlinear, but roughly equal from the two samplers, so the effects cancel.

In my case the only problem with the AD8302 was asking it to work just beyond it's dynamic range spec. With the addition of the limiters I got 30db more range. I can key the mike and not speak, and still get a solid phase reading now.

But Dr. Best claims to be able to superpose powers to get more than the
sum of the two input powers. See my reply to him.

> I have never said that you could do what Cecil is suggesting above - i.e.
> take two separate sources and combine them such that they deliver more total
> power than the sum of the power being delivered by each.

Steve, you say you can do it in your QEX article. Here's the quote: "... the forward source power of 92.831 W combines in phase with the re-reflected power of 0.555 W, resulting in a total forward traveling power of 107.736 W." If you can do that with a 92.831W wave and a 0.555W wave, why can't you do it with two 100W waves?

> Superposition
> principles can be simply applied to the voltages and currents in this system
> to demonstrate that this is not possible.

You cannot have it both ways, Steve. Either it is possible to combine two waves of 92.831W and 0.555W to get 107.736W or it is not.

In your article, you say the "two rearward traveling waves 1 and 2" cancel. We know that is reflected power because their voltages and currents are 180 degrees out of phase. Where does the energy in the canceled waves go, Steve? Could it be that the destructive interference in those two canceled waves is exactly the constructive interference energy you try to disguise in your energy equation? Of course it is! The constructive interference energy in your equation is really re-reflected power.

An impedance discontinuity is symmetrical. Your equation of:

P1 + P2 + constructive interference = Pfwd2

has to be perfectly matched to the equation on the other side of the impedance discontinuity. Anything else violates the conservation of energy principle.

P3 + P4 - destructive interference = Pref1

It was originally used as a receive only antenna for 160 and possibly 80.
Transmit on it? Probably done better with a .5 wave of mini 8 to a dummy
load. Or just stick a light bulb on the end. May do pretty good
locally...grin.

That might be a way of referring to what the FCC calls "Class B"
airspace. It's the airspace in and around major U.S. airports.

There's a sort of broad, flat "funnel" shape defined around such
airports, covering the airspace where commercial airliners fly on
their way into and out of the airport.

Air traffic within Class B airspace is restricted in a number of
ways. You have to be carrying a radio which can communicate with the
air-traffic controllers, you have to have certain other equipment if
you're flying under "instrument flight rules" (e.g. when visibility is
poor), and if I recall correctly (I'm not a pilot) you have to
establish radio contact with the air traffic controllers and gain
permission to enter the airspace. There are a bunch of other regs
which pilots have to know about.

Thats probably about the going rate at hamfests. Just depends...I
bought a few 1930's qst's for 2$ a piece, but thats been a while. From
that person, I got 50's issues for 1$. But I have loads of them I got
free from people that decided to clear them out after 40-50 years. I
have a good few from the 40's, many in the 50's and 60's. Some issues
are probably worth more than others. IE: one of the 1955 issues has a
reproduction of the first QST inside it. Also your special issues like
the one after Pearl Harbor where they closed the ham bands down with
the yellow insert. Jan 42 I think.. I have two of those...:/ I've got
a july '35 issue with a picture of a mobile setup on it. Used kind of
a tripod mounted whip on the back fed with twisted pair wire. I think
the call on the spare tire says W9MSY. There is also a pix of another
experimental mobile setup . The vehicle was completely copper clad.
H.P. Maxim was still the president when that issue came out. Those old
QST's are interesting reading. Think bootleggers are a new thing? Not
hardly...In 1935, there were more bootleggers on 5m, than licensed
hams by the complaints I read. MK

For short wave listening you can run a wire out from wherever your receiver is to the nearest tree or other support. For receiving, the length isn't critical. Usually SWL's just run as long a line as possible and connect it to the back of their receivers. Heck, when I lived at home with my folks when I was a kid I just ran some bell wire around the perimeter of my room. I tacked it to the baseboard molding and ran the free end to my SW receiver. It worked great!

If your getting interference from a really close by transmitter; their might not be much you can do, if their transmitter is overloading your receiver's front end. However, if the offending station is using a vertical antenna (tower) the a horizontally polarized antenna like a longwire or dipole might help just a wee bit.

Hi Rich,
Thank you for the mailbox notice. I`ll try to clear it.

I am impressed with what Rich, K2CPE did with a low horizontal loop using low power on his first attempt. Ushuaia is near enough to the antarctic circile, and a very long way from North America. The first day of summer is a couple of days away. Daytime temperatures are probably above freezing at times. There is no complete darkness during a very short night, there is an hour or two of twilight.

On the warmer north side of the island, there was record breaking high temperature during the middle of one or two of those long days while I was there. It reached 72 F degrees. I was there one winter, too, and that is more problematic. July is a booger. Cold and you only glimpse the sun for a while.

Radio reception is very good because the noise is low and you are surrounded by oceans. Lots of severe storms but zero lightning. It`s too cold for thunderstorms. South African and even U.S. stations are well recived on medium wave. As Rich demonstrated, shortwave is excellent.. Oilfield hands had trouble with SSB. Couldn`t keep hands off speech clarifier and channel change knobs so they often missed each other when trying to communicate. I pulled the stuff out of land vehicles and replaced it with VHF FM and some tall towers for the fixed stations. Much improved results! I could listen to stateside AM stations with my little handheld Hitachi portable, the noise was so low. We could often talk to an oilfield supplier in Midland Texas on a 33 MHz 5W FM Motorola Handitalkie we had connected to a vertical dipole about 30 feet off the ground. This was due to the solar cycle, of course.

We had a visit from a "Little America" team much farther south which was listening to and recording "whistlers", low frequency anomalies resulting from solar flux. I think they enjoyed a short break from the deep freeze.

Best regards, Richard Harrison, KB5WZI

Exactly this I had in mind. Maybe my English is not so perfect to
express my mind exactly. Moreover, the term "a tuner" is often used
for a more complex circuit, at least a Pi-network, perhaps combined
with a SWR meter, maybe even with automatic microprocessor balancing.
Such a tuner would be really far too much for the aim.

So why don't they insist that batteries are removed from phones and put in a
pocket whilst the phone is put in the bag in the hold....

I know some phone's aren't designed to have batteries removed easily, but
that's no excuse is it !

There could be an RX designed to be fitted to aircraft so that as people are
boarding the TX of the mobile would be picked up and amplified for the crew
to hear, - you know like when a mobile's poling the network when it's next to
a speaker.... I know they don't do it all the time but surely there would be
some way to jam the signals or do something to make the phone's no the
aircraft pole the network before the engines are started....
An announcement could then be made that someone has a mobile in their pocket
that's not turned off and the aircraft won't be leaving til it's sorted !!

Just thinking aloud to the keyboard.....!

There's always an answer...

You could download the latest 5.0 version, but the Genetic Algorithms
are only included in the new to release 5.1 version. I hope this will
be in a few weeks. This 5.1 version is not yet officially available,
because I am not yet quite happy with what characteristics to specify
for optimization and I will have to do some further testing to deliver
a relatively failsave package.

> optimized for the height and ground quality it will be implemented in. This is

> in half, they were OK.

Ground conditions can be specified, but because 4nec2 is based on
nec-2 it's not possible to specify sloping hills. You could use a
'two-stage' ground conditions, as if you were on a high plateau, but I
do not think this will addequate model a sloping beverage because the
beverage requires a relatively constant distance between the wire and
ground.

> Another factor is antenna structures (towers, guy wires) and other hard to
> model stuff (houses, electrical wiring, etc.) within couple wavelengths that
> contribute to distortion or enhancement of the array performance.
> Are we going too far? :-)(

If you take the time to collect all the real-world XYZ coordinates and
if you have enough memory on you machine, its throughout possible to
model them and see how they affect the pattern.
For instance I once modelled almost all the wiring, fences and gutters
in, on and around my house to see what effect they had on near- and
far-field pattern.

> I didn't have the chance to use 4NEC2, I hope to do that soon, I wonder if
> others have used it and their comments.

Some like it, some don't. I must admit it's more difficult to use than
for instance EZnec, NecWinPlus or MMANA (the latter being based on the
mininec kernel) because it requires some knowledge about the nec-2
syntax. But it has the advantage of being able to use most of the
official nec-2 cards. It can handle a large number of segmetns and has

some features not available in the other packages. If you don't
require those features I would suggest to choose one of the more
traditional packages.

> Is there coordinates "translation"
> tool for dimensions between various programs? That would help to compare
> results and fine tune the designs.

It can read nec-2 and AO (antenna optimizer) or Nec-wires files. To
convert between other modelling packages use the MuliNec freeware by
AC6LA(www.qsl.net/ac6la/multinec.html)

Arie.

5091. Practical experience on using burried radials, insulated or not ?

Newsgroup: rec.radio.amateur.antenna

Hello...,

During some years now I am using both used insulated wires and none-insulated wires for my burried radials. I use both some 40 radial wires and a number of more deep ground rods (6m long copper conduit-pipes)

Anybody having practical experience on the difference between using insulated or none-insulated burried radials.

I would say, use none-insulated wire, because it is in more contact with the surrounding earth. But during the years it is more subject to desintegration and oxidation and I dont think copper-oxide is such a good conductor.

Arie.

Reasonable speculation as there are manufactured copper-oxide rectifiers.
But the trepidation is not necessary.

Don`t worry about buried bare copper. Radio station I worked in back in 1949 already had a dozen or so years on its bare radials. Station still operates using the same radials and with undiminished field strengths as measured at designated points distant from the station. This is not unusual. 10,000 AM radio stations can`t be wrong. Many have 75 years on their bare radials which are unaffeced in their practical efficiencies in all that time. Sure you can find some exception in all those examples, but they are few, not the rule.

Two very narrow conical beam orthogonal EM waves travel in space. They intersect. One wave has a power density of 92.831 W/m^2. The other wave has a power density of 0.555 W/m^2. The waves have the same polarization and they are in phase. What is the resulting power density at the point where they intersect?

Don,

My offhand guess is that your existing antenna does not have anywhere near
16 DB gain, CH19 being near the low end of the band. You might want to do a
quick and dirty test, cut a folded dipole for CH19, and compare that to your
present antenna. Double check this, but I think the CH19 carrier is at
501.25 MHz. The length of the dipole would be about 11-1/8 inch.

Joseph,

What you need is a trap tuned to the BC station. If it is an AM station you can get by with a high pass filter. What is the frequency of the station? Is there a ground terminal for the antenna? What is the lowest SW frequency that you want to receive?

Yes, and what is the price of eggs in Macao?

I can add powers in an antenna for a power gain of 100 times guite easily. This is concentration of power which otherwise might go in many directions into only one general direction.

The possibilities of power gain between two powers with two possible directions as on a transmission line are limited as a maximum total power to the arithmetic sum of the two powers. Pao, pao, queijo, queijo! Mais nada!

> 16 db of gain.

I doubt you find gain information on the Radio Shack antennas. It's possible that their top of the line UHF only antenna will give better reception than the UHF/VHF combo.

The RS UHF antennas are corner reflectors with many yagi-like directors. I have used those antennas with good results, but not for stations 100 miles away (except during enhanced propagation conditions).

Channel Master CLAIMS "approx 14 dB gain" for their corner reflector UHF antenna. See:
http://www.starkelectronic.com/cmuhf.htm I'm always a bit skeptical of antenna gain claims, especially if the don't specify dBd or dBi, and espescially for broadband antennas.

Probably the best bet for a UHF antenna would be a parabolic reflector type. I've see some with ~7 foot reflectors. See:
http://pages.cthome.net/fmdx/Ant_recvrs.html (Scroll down to bottom)

or

http://www.sateng.com/catalog/category_mfg_search.asp?category=Antenna%20Systems&mfg=Wade%20Antenna%20Products

or

http://dxworld.com/uhf_ant.html

Since Channel 19 is at the low end of the UHF band, I think a good long boom yagi optimized for CH 19 would be a good choice.

Remember, gain is only part of the problem. You must have something close to a line of sight path to the station. If there are large hills or other obstructions in the way, it will be very difficult to get a station 100 miles away. Antenna height is at least as important as gain. Low loss coax is also important (at least RG-6, or see if you can get some discarded "hardline" from the local cable company). I doubt that you're ever going to get a snow free picture at that distance though.

You'd think there was after reading Cecil. I believe Dr. Best is
trying to teach Cecil the correct way to add electromagnetic
wave intensities. The problem is, that if you exclude some of
the information when you're doing a superposition calculation,
you can claim that the calculation violates the conservation of
energy laws. This is what Cecil is doing in his obsessive ranting
concerning the addition of powers in a transmission line. The object
seems to be more to win an argument through the time-honored,
but wrong, if-you-caint-answer-me-on-one-defined-strictly-by-me-
question, then I'm automatically right. This was the technique used
by the kids in my home town when arguing with other kids over
such overpowering questions such as "Does God exist?" (You cain't prove
he don't.) and "Are black people inferior?", spawned by
self-ordained hick ministers in Sunday school. It didn't work well for
those kids then, and it doesn't seem to be working for Cecil now.
73,
Tom Donaly, KA6RUH
(P.S, Those kids didn't use the term "black people" and neither did
the ministers who got them going.)

Please do not confuse 'power' and 'energy'. If the power is constant over time and the situation is steady state, then you can jump back and forth without being incorrect. But it is best to be very clear and use exactly the right words always to avoid confusion.

I'm sure that you know that already - I'm just documenting it for NG posterity.

Yes, but it's got to have a low noise figure. And if it craps out he's got a problem. When I was getting TV over the air, I had a preamp in the attic just ahead of my splitter.

Just remember that these are photocopies.
You can search the index but that is all. I'd like to go over the
articles with OCR and put them in a database so I could search the
entire list for words, topics, phrases...etc. Unfortunately that is
more time than I'm willing to devote to the project.

Source record: 128746

I don't remember any particular articles that I referenced, but I got a lot of good info from a couple of manufacturers websites...namely Analog Devices and Mini Circuits Labs. If you interested in an auto tuner, you might also want to check out the SGC website...they have the manuals for their tuners online, complete with schematics. I got some ideas from the circuit for the SG-239 for my auto tuner design, although I didn't wind up using their phase detector.

"Harris"
> Yes, but it's got to have a low noise figure.

As you probably know, every dB of cable loss between the antenna and the first preamplifier is another dB worse noise figure. It doesn't take much coaxial cable to effectively destroy the noise figure of a good preamplifier. For TV frequencies (especially the higher channels), the math is compelling and logic forces the preamplifier up the tower.

> And if it craps out he's got a problem.

Or a ladder.

> When I was getting TV over the air, I had a preamp in the attic
> just ahead of my splitter.

You're absolutely correct that if you don't *need* it up the tower, then the attic is good location (perhaps 30 feet, several dB, better than the basement). It depends if the signal is weak or not.

A long time ago, I built some NBS Yagis (6-element IIRC) scaled to VHF TV Channel 8. They 'kicked dust in the face of' some very large commercial TV antennas, but they only worked on one channel of course.

Any electronic device *may* cause interferences. That is not to say
that they do, or will. The same device *may* affect the systems in
one aircraft and not another. When they interfere the degree of
interference is usually different between planes.

Rewording a bit.
Mobile phones may be a threat in some instances. In the case of some
instances the CAA will play it say and just say they are a threat.
Here in the US they are supposed to be turned off, but people forget.
Laptop computers are one of the worst radiators and sources of
interferences. However, if they band those they will likely lose a
goodly percentage of their business travelers.

>
>Tests carried out by the CAA on board two aircraft found that phone

That will basically be the only way to prevent them from being turned
on...course they'd have to be banned from checked luggage as well.

"Although" all they'd have to do is require all cell phones be sealed
in a foil bag. Even at full transmit power they'd not interfere with
anything.

>`But we have to face the fact that accidents happen and that mobiles which

>Source: GUARDIAN 21/06/2000 P11

Although they used some poor choices of words the article is
essentially true. It just doesn't include other devices such as
laptops which are potentially more of a problem than the cell phones.

Hold it! Hold it! Hold it!

There is no assurance that the reflected WAVE is 180 degrees out of phase!! A low impedance, relative to Zo, produces a negative phase shift in the reflected voltage wave and NO phase shift in the reflected current wave. A high impedance, relative to Zo, produce a negative phase shift in the current wave. The magnitude of the phase shift depends upon the complex impedance of the load.

A reflection coefficient is a complex value and can have any phase relationship depending on the resistance and reactance in the load. A Smith chart shows all possible reflection coefficients.

The reflected current and voltage can have any load factor, cosine theta, between zero and one. So, the reflected WAVES can have any power factor and must be treated as both POWER and Reactive Volt*Amperes [VARS].

J. Harvey wrote:
"Please do not confuse "power" and "energy".

That seems a polite accusation, not a caution.
Please identify an instance in which I`ve made the wrong word choice and I`ll correct it.

For the benefit of some who may be rusty on the difference, energy is measured in joules which are also called wattseconds. Joules are one of those unnecessary terms such as Hertz which we would be better off without. Hertz is identical to the descriptive term "cycles per second" which leaves no doubt as to meaning. CPS has two less letters than Hertz. The other name for the joule is the wattsecond which also leaves no doubt as to meaning. At least the term Joule has 5 less letters than Wattsecond! The wattsecond, as is obvious, is the product of watts and seconds. So, watts times seconds equals joules.

Thus, watts are joules per second, as Cecil often correctly uses in his postings in this newsgroup. Joules per second, where I would have just said watts, is OK by me. To each his own! The advantage is, Cecil would probably not say wattseconds per second. To me anyway, wattseconds per second sounds as an acceleration-like term. Don`t point out that there is a "per" missing in wattseconds per second. It`s a waste of bandwidth.

As long as you don`t get the joules/sec equals watts wrong, there should be no confusion.

Best regards, Richard Harrison, KB5WZI

> where they intersect?

True to form, you divert the issue with irrelevant examples of ever
increasing difficulty. Are you afraid to give me straight answers
to my simple questions?

According to your QEX article, since the beams are orthogonal to each
other, the two powers will simply add without destructive or constructive
interference.

Here's my personal corollary to the conservation of energy principle.

****
* W5DXP's corollary #1: Given a lossless impedance discontinuity in a
* lossless transmission line, any constructive interference on one side
* of the discontinuity must be accompanied by an equal magnitude of
* destructive interference on the other side of the discontinuity and
* vice versa. Interference energy flows across the discontinuity from
* the destructive interference side to the constructive interference side.
****

The superposition principle predicts four component powers from Pfwd1
and Pref2. You call them P1, P2, and the "two rearward traveling waves"
which I will call P3 and P4. So here's the rest of your equations, Steve,
you know the ones you left out of your article for obvious reasons?

You say: If the phase angle between V1 and V2 is zero, then
Pfwd2 = P1 + P2 + 2 Sqrt(P1) Sqrt(P2), forward power toward the load.

But since the phase angle between V3 and V4 is 180 degrees, then
Pref1 = P3 + P4 - 2 Sqrt(P3) Sqrt(P4), reflected power toward the source.

An impedance discontinuity in a transmission line is symmetrical. Your
term, + 2 Sqrt(P1) Sqrt(P2), is constructive interference energy. It is
exactly equal in magnitude to the - 2 Sqrt(P3) Sqrt(P4) destructive
interference energy term, i.e.

+ 2 Sqrt(P1) Sqrt(P2) - 2 Sqrt(P3) Sqrt(P4) = zero

which clearly indicates that your constructive interference energy
is being supplied by the destructive interference between two reflected
waves, i.e. your constructive interference energy is *re-reflected energy*.

That makes about a dozen assertions in your QEX article false. Did you
think nobody would notice?

Tom, maybe you can answer my question. How do you add electromagnetic wave intensities to obtain more energy than exists in the two waves without destructive interference happening somewhere? Doesn't the conservation of energy principle apply to electromagnetic waves? Is it possible, as Dr. Best asserted last week, to obtain constructive interference without a corresponding destructive interference? If it is, you guys have just invented perpetual motion.

The power we are talking about *is* energy in motion. One joule in one
second is still one watt, last time I looked.

Wow! What a concept.

Say... is that true, even if that same Joule keeps coming back around again
and again
because of multiple re-reflections, each time passing by in the opposite
direction?

I'm sceptical... Sounds kinda like perpetual motion to me. :-)

Of course it's true, by definition, Peter. Consider a superconducting ring in which one joule passes a point every second. That's one watt at that point. You can measure that same one watt in 1000 different places around that ring as long as you don't dissipate any of it. Just to refresh your memory, from the IEEE dictionary: "power - the rate of generating, transferring, or using energy". Note "transferring energy" which is exactly what a transmission line does both in the forward and reverse directions. Forward energy flow and reverse energy flow *is* power, by IEEE definition.

Arie:

I can further expand on Richard's comments. I had occasion in 1991 to make some measurements in Puerto Rico at an establishment which was out in the swamps just west of Toa Alta. The ground mat and radial system was constructed of bare 10 ga. Copperweld, and had been in place about 10 years. The deep thinkers were concerned that the thin copper covering was eroded away and the whole thing needed replacing. We looked at the ground mat, some 40 acres of it, and found a few broken welds, but no obvious widespread damage to the wires themselves. We also noticed that there were a lot of remnant pieces of the Copperweld, short pieces cut off and left lie where cross connections and splices were made. A large quantity of these were taken back to the labs and there copper thickness was measured, and no loss could be measured. Now, I don't know if you live where the soil is more corrosive than Puerto Rico swamps, but copper longevity there appears to be as long as anyone would need. Unfortunately, Hurricane Georges destroyed enough of the site in 1999 that the experiment ended, so I have no follow-on data, but there was still no apparent damage to the ground mat in November 1999, and there was no cathodic protection either, by the way.

The insulation on the wires will effect the length to some small ammount , maybe only an inch or two. You probalby will not notice the effect. If the antenna does seem to resonate slightly lower in frequency , it may be the insulation, cut an inch off each wire and try again. You may notice a simiar effect due to the wood. Also the wood should be well water proofed or things could change if the wood is wet and the wire is layed on the wood..

If you look at the two slits and shine a light behind them you'll get an interference
pattern of dark and light stripes on a plane surface held in front of them. At any
point on the surface, the intensity will be proportional to (E1 + E2)^2, but, if you take
the average intensity over all the points on a line perpendicular to the stripes you
should get an intensity proportional to E1^2 + E2^2. This is a lousy explanation, but you should
get something better out of a college text. In the case of a transmission line, if you
measure the power in your lossless line, anywhere, taking into account _all_ the voltage and current
waves, forward and backward, you should find the power the same wherever you look, and
the power going into your transmission line should be the same as that going out.
Calculating the power in the individual waves and adding them together is liable
to get you in trouble, especially if you're consistent and take the square of each
individual reflected voltage and add them all together instead of adding all the reflections together
for a specified direction and then taking the square.

Actually, this is as good an illustration as any of what I am getting at.
The energy in those two waves is fixed. Here's what you said earlier:

> The total forward power increases as a direct result of the vector
> superposition of forward voltage and current. This DOES NOT require a
> corresponding destructive interference process (reduction of power
> elsewhere) to balance the law of conservation of power ...

So Steve, using your EM space wave example above, please explain how you
can achieve constructive interference without a corresponding destructive
interference occurring somewhere else. How do you manage to create energy
just when and where you need it?

You apparently can make all the light interference rings brighter without
any corresponding dark rings. Could you video tape that experiment for us?

Yes, yes, yes, but Dr. Best can do that experiment without any dark rings
appearing. All of Dr. Best's rings are bright. How does he do that?

>> Dr Best said:
>>> The total forward power increases as a direct result of the vector
>>> superposition of forward voltage and current. This DOES NOT require a
>>> corresponding destructive interference process (reduction of power
>>> elsewhere) to balance the law of conservation of power ...

Note he capitalizes "DOES NOT require ... destructive interference". That's
pretty clear, Tom. All of Dr. Best's rings are brighter than the average
brightness. None of Dr. Best's rings are darker than the average brightness.
He says there is no destructive interference, only constructive interference.

> Calculating the power in the individual waves and adding them together is
> liable to get you in trouble, ...

But that's exactly what Dr. Best did. He says 75 joules/sec combined with 8.33
joules/sec equals 133.33 joules/sec. He obtains power gain out of those two waves
without any destructive interference occurring. Exactly how does he do that?

In the places I've seen, the corrosion can vary wildly from one extreme
to the other.
In eastern NC where I once lived, the soil would eat up anything metal
in short order. I work in cable TV and we had the cheapo ground rods
literally disappear below ground. Here in the Caribbean copper suffers
only mildly but aluminum and certain other metals go quickly in the
air...less rapidly in the soil.
Its hard to place a definite answer on this question.

The word transfer also has a definition and a physical implication - one
you may not be employing correctly here. What exactly is this
transmission line transferring this particular energy TO, Cecil? I
claim that it's not tranferring that energy to anything. I thought
that's also what you were claiming.

But perhaps the IEEE dictionary also defines the concept of power
storage (as opposed to energy storage).

> Please identify an instance in which I`ve made
> the wrong word choice and I`ll correct it.

I copied the pair of sentences - again... - at top. It seemed that you were trying to form an argument. Therefore, the juxtaposition and wording of those two statements could quite reasonably be (mis?)interpreted as a statement from you that the first follows from the second. It doesn't.

Furthermore, the first sentence is arguably wrong. One can violate "power conservation" and "power addition" by simply throwing a brick against a cement wall. One cannot violate EM theory by throwing a brick against a cement wall.

There is no 'Law of Conservation of Power' (nor of '...Power Density'). Energy is conserved (but can certainly be 'misplaced' - as heat for example), but any sweeping and general statements about Conservation of Power and "Power addition" being "fundamental" are not correct as general rules.

...Going back to your original posting...

"Richard Harrison"
> The possibilities of power gain between two
> powers with two possible directions as on a
> transmission line are limited as a maximum total
> power to the arithmetic sum of the two powers.
> Pao, pao, queijo, queijo! Mais nada!"

If you'll allow me a particularly complicated form of transmission line (arguably fair if you think about it...), then the quick counter-example is the technology used in Pulse Compression Radar (a classic example in support of my point about there being no such thing as 'The Law of Conservation of Power').

I realize that I'm nit-picking. And I'm referring to the generalities - not to any particular case where power is conserved and power addition works.

Happy Holidays.

It's transferring the energy to the load where part of it is rejected.
The rejected part is transferred back along the T-line to the match
point where it is re-reflected by the impedance discontinuity and by
the interference pattern.

Isn't 'displac(ing) the position of the minima' an indeterminate phase shift?

My copy of Terman, also 1955 (and 1948), p 93 states under REACTIVE LOADS [the same paragraph you are quoting]: "... the phase angle of the reflection coefficient will depend upon the ratio of the load reactance to characteristic impedance." This is followed by your statement regarding the displacement [phase shift] of the minima etc.

After the initial 'displacement' [phase shift] the 'normal 1/2 wavelength characteristics repeat as you state.

At the bottom of P 94 Terman continues: 'When the load impedance does not equal the characteristic impedance the phase relations are complicated by the presence of the reflected wave. The phase of the resulting line voltage [or current] then oscillates [[my words 'dynamically varies']] about the phase of the voltage [or current] of the incident wave ..."

This characteristic then exhibits the 1/2 wavelength characteristics.

A resonant antenna is RESONANT only at one frequency where the load impedance is purely resistive [no reactive component]. Very slight deviations from the resonant frequency introduces either capacitive or inductive reactance and therefore the reflection coefficient changes from a REAL number to a COMPLEX number having both amplitude and phase components.

So, if I have any VSWR at the load I have an initial phase shift based upon the ratio of either inductive or capacitive reactance to the Zo of the line. This phase shift is 1/2 wavelength repeatable.

So, my initial statement regarding your statement of a 180 degree phase shift is still accurate. A 180 degree phase shift is valid ONLY for resistive loads. ANY phase shift is possible IF a reactive component exists in the load [for all practical ham purposes we have a complex reflection coefficient and a phase shift that varies as we tune across the band].

That's a regretable error (using the word "principle" in connection with "conservation of power"). Be sure to report it to the author or publisher.

Copyright 1950. :-) The kind of power that exists in a transmission line
is simply the energy in joules passing a certain point in one second. Those
joules are conserved.

Energy is fixed?

What we measure and discuss in our examples is average power. Energy is the time integral of power. Power is the time derivative of energy. Presuming that there is some value of average power, the energy actually increases with time. With increasing time, energy - in terms of energy delivered to a load or energy passing a point in space - is not fixed.

Considering either of these EM waves (separately) passing a point in space, average power or power density is the constant (fixed). In terms of energy, this translates to the following: the time rate of change in energy is constant - the derivative of energy is fixed, not the energy itself. The energy passing this point increases with time.

>
> So Steve, using your EM space wave example above, please explain how you
> can achieve constructive interference without a corresponding destructive
> interference occurring somewhere else. How do you manage to create energy
> just when and where you need it?
>

So, do you believe that when a multipath fade (destructive interference) occurs in a communications link, there must simultaneously be a corresponding multipath enhancement (constructive interference) somewhere else as a balancing act? It sure sounds like you do.

Going back to our two intersecting EM waves:

When these two waves intersect, the total power density at the point of intersection increases in proportion to the square of the resulting total field strength. In terms of energy: the time derivative of energy

increases.

Energy has not been "created" as you keep insisting in your interpretation the problems discussed. It is the rate at which energy is extracted from the resulting wave that increases.

In this case "the wave" is the net wave (field strength) resulting from the combination of two intersecting waves. At the point of intersection, the power density increases - the rate at which energy can be extracted from the wave increases. The law of conservation of power is not violated because any power dissipation at this point would not exceed the power delivered at this point.

Think about this for awhile. My time allotment for the week has been exceeded. Vacation time ...

J. Harvey wrote:
"One can violate "power conservation" and "power addition" by simply throwing a brick against a cement wall."

Look up inertia in your dictionary.

Mine says:
"Physics, a. that property of matter by which it retains its state of rest or uniform rectilimnear motion so long as it is not acted upon by an external force. b. an analogous property of a force: electric inertia.

By the IEEE definition of power, power is energy in motion in one case. By the rule of inertia above, power must remain unchanged unless acted upon by an external force.

An oscillatory circuit continues oscillating uniformly forever if its uniform energy motion isn`t sapped by electrical and heat losses or the power isn`t boosted from outside by some impetus. This is, in a sense, conservation of power.

A brick striking a wall has energy of mass and velocity. It acquired the energy through application of power over a given period. When this energy is converted into heat or otherwise transferred, the energy released over the time in which this release takes place, the work done, equals the work done to give the brick its energy.

Power is the rate of doing work. Energy is the sum of the power applied over a time period.

When the time period is a constant, power and energy are interchangeable using the proper scaling factor.

A brick may come to rest more quickly than it was brought up to speed. In this case, the power in the flying brick`s arrest is greater than power applied to bring the brick up to speed. But, it was applied over a shorter period of time to bring the brick to rest. The energy released equals the energy given to put the brick in motion. This is not conservation of power, as we have energy storage in the mass of the moving brick

Our discussion wasn`t about flying bricks. It was about electric waves on transmission lines where the wave velocity is the same in both directions. Even the electrons which may be excited in the process all have the same mass as far as anyone knows. For our purposes it makes no difference whether we use power or energy, if we use the right scale. We have no storage other than the energy contained on the transmission

line. We are not storing energy in the line for rapid release as in a flying brick.

J. Harvey`s argument does not fit waves on a transmission line for our application.

Best regards, Richard Harrison, KB5WZI

5148. Re: HP 4815A vs HP 8405A ???

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-21 02:32:56 UTC
From: Rick Karlquist <richard@karlquist.remove.this.com>

Source record: 128686

The 4815 only measures impedance, nothing else.
For impedances with a magnitude much less
than 50 ohms or, especially, much greater than
50 ohms, it is much more accurate than network
analyzer based instruments. It will also tell you
the phase quite accurately, although not well
enough to measure Q>10. It has a frequency range
up to 108 MHz. It is probably unsuitable for
many antenna measurements because of the low
signal levels involved and the harmonic sampling
used. No way to work around this AFAIK.

The 8405 measures complex voltage. Provide
a source and a directional bridge, and you have
a network analyzer of sorts. It will work well
near 50 ohms, and degrade away from there.
Unlike the 4815, you can drive the antenna with
high signal levels and protect the 8405 with
filters and/or attenuators. This can get around
the harmonic sampling problem. Also, the 8405
goes to 1 GHz.

Both instruments are not exactly "portable",
another disadvantage for antenna work.

Hope that helps.

Where does the average increased energy come from, Steve? The rate of average
energy flow in the two waves is fixed. Where does the average increase (constructive
interference) in energy come from if not from a decrease (destructive interference)
in average energy elsewhere? You cannot get 50 watts of constructive interference
when superposing two waves unless there is 50 watts of destructive interference
between two other waves.

Your watts per square meter are *average* values. If you increase the
the average watts per square meter somewhere, you are violating the
conservation of energy principle unless you decrease the average watts
per square meter somewhere else. That's why we get bright and dark interference
rings. I've never seen just bright rings, have you? Yet you are arguing that you
can indeed come up with nothing except bright rings. In systems of the type we
have been discussing, there is no additional source power available. Constructive
interference must be equaled by destructive interference.

Steve, VE9SRB wrote:
"So, do you believe that when a multipath fade (destructive interference) occurs in a communications link, there must simultaneously be a corresponding multipath enhancement (constructive interference) somewhere else as a balancing act?"

All the power has to go somewhere. When it doesn`t go one place, of course it goes elsewhere.

Terman says:
"Fading of a single sky wave can be explained by the fact that ionospheric reflecting surface is not perfectly smooth, but instead exhibits irregular variations in ionization density. The effect is like a large number of separate components each of which contributes a small component to the total signal."

Ever reflect the sun with a mirror illuminating various spots with the reflected rays?

My observations with a triple space diversity receiving system leads me to believe Terman had it right. When one antenna isn`t being favored with signal, chances are the other antennas are getting a pretty good signal. In fact, even when fading is fairly severe, with three sepatate antennas and receivers, and a good combiner selecting the best of the crop, chances are good that the output of the system is smooth and continuous.

That is evidence to me that the signal that fades away goes elsewhere.

Dave Schrader wrote:
"When the load impedance does not equal the characteristic impedance the phase relations are complicated by the presence of the reflected wave."

Yes. Reactance shifts the SWR pattern. It has the effect of adding or taking away degrees of transmission line feeding a mismatched load.

The 180 degrees happens at the reflection point as a result of a phase reversal of either the volts or the amps upon the reflection, but not the reversal of both.

The transmission line enforces Zo on both the incident and reflected waves.

The individual waves maintain their in-phase or out-of-phase relations between volts and amps during their propagation on the line. SWR is a manifestation of both waves seen together, not the individual waves which are well behaved.

Best regards, Richard Harrison, KB5WZI

Hi Dick,
I was writing in terms of militias, as Fred presented them. I
don't
think that ordinary people who want to protect themselves should have to
rely on the second amendment. If enough of their fellow citizens think it's a
good idea to allow guns in their particular society then they should be allowed
to
put the matter to a vote. Evidently, some localities have done just that.

For the single wave, I agree. For the single wave, acting independently, the J/s are established by the boundary conditions at the source.

The question we are considering is what can happen when two waves combine.

The waves are essentially a V and I established by the Z of the medium. How many J/s can a constant V supply? Its entirely a function of Z and never violates the law of conservation of energy. If Z is fixed, we can increase J/s by increasing V. However, the increase in J/s is a function of the square of V - the increase in J/s is not a one-to-one relationship with the increase in V.

The wave interaction is analogous to two series V across a fixed R. The J/s total is greater than the sum of the individual J/s (considered acting alone on R)

We disagree on the interpretation of what is physically happening when two waves combine and I guess its best to leave it at that. I can demonstrate the results of the orthogonal EM wave interaction in a lab - so there's no interpretation problem from my perspective. I'm trying to think of a similar experiment with light - I'll let you know if I can come up with something.

I will leave you with one point and several questions:

Presume the two orthogonal waves that intersect are of equal amplitude and 180 degrees out of phase. My interpretation is that the waves cancel (at the point of intersection) and that the net energy extracted from the resulting wave as a function of time is 0 (at the point of intersection). The waves are still there (they do continue on there way after they intersect) but no net energy as a function of time is being extracted from the waves (at the point of intersection). Your interpretation of the problem requires the "canceled energy" to go somewhere. Where does it go and how can I measure where it goes? Also, if the energy in the individual waves goes somewhere else, how does the energy also continue on past the point of intersection?

Happy Holidays

All of the replies in this thread have focused on the longevity of buried bare copper wire. I think the larger question is whether or not bare wire give better performance than insulated wire. I would not think so. The ground plane is provided by the wires, not the surrounding earth.

It may be that in commercial installations with many ground radials, the decision was based on the low cost and mechanical strength of copperweld.

"I think the larger question is whether or not bare wire gives better performance than insulated wire."

The broadcaster`s decision to use bare wire isn`t primarily based on the cost of insulated wire. One listener is very valuable to a broadcaster. If more costly ground systems would bring more listeners within range in significant numbers, you would see the money spent on the better ground system in most cases.

The value of ground contact with the ground radial system depends on frequency. At 1 MHz, bare wire at the earth`s surface needs contact with the soil to rob the soil of displacement current between the point of soil displacement current contact and the antenna drivepoint at the base of the tower. The soil contact point for displacement current must be near a radial for high efficiency.

The nearer the tower, the greater the displacement current, and fortunately the radial coverage is denser too by design nearer the tower. Displacement current needs to find a radial nearby to limit current travel distance in the soil.

Terman says:
"At broadcast and lower frequencies the ratio of capacitive reactance of the earth to the earth resitivity---is considerably greater than unity, so to a first approximation the earth can be regarded as purely resistive.----Conversel;y, at frequencies of the order of 10 MHz and greater, the impedance represented by ground (but not sea water) is primarily capacitive---."

At high frequencies, the earth`s resistance is bypassed by its capacitance.

Best regards, Richard Harrison, KB5WZI

This is all true. The question is where do the additional joules/sec come from that support the squaring of the sum of the voltages? They come from constructive interference as I assume you know and will agree to. What you are missing is that if there is constructive interference, there must be an associated equal magnitude destructive interference. At a match point in a transmission line, the destructive interference on one side of the match point has to equal the constructive interference on the other side. In a light interference pattern, if there are bright rings, there must also be dark rings. The conservation of energy principle will not allow anything else. If we could see the EM waves in the transmission line, you are saying that you can cause a bright spot without causing a dark spot somewhere else. That's impossible, Steve.

> The wave interaction is analogous to two series V across a fixed R. The J/s
> total is greater than the sum of the individual J/s (considered acting alone
> on R)

OK Steve, we set up an experiment which causes interference (superposition) between two light waves originating 20 light years away. The source has no way of knowing what we are doing and has no way of adjusting its E and H fields to compensate for our experiment. The interference is completely localized. Tell us again how that is analogous to two series V across a fixed R and we can get more joules/sec out of the superposition of those two waves than exists independently in those two waves.

You have made this same mistake for more than a year now. In a wave, the ratio of V/I (or E/H) is fixed. The maximum joules/sec is fixed at V*I. You simply cannot get more joules/sec out of superposition of two waves than exists independently in the two waves without supplying additional energy from somewhere. That somewhere, in this case, is constructive/destructive interference. Your statement that you can have constructive interference without an associated equal magnitude of destructive interference is simply false. You cannot have all bright rings in your light interference pattern even if you say you can. Some of the rings have to be dark.

> We disagree on the interpretation of what is physically happening when two
> waves combine and I guess its best to leave it at that.

Your way requires a violation of the conservation of energy principle. My
way doesn't. There is no contest. Delude yourself to your heart's content.

> I can demonstrate
> the results of the orthogonal EM wave interaction in a lab - so there's no
> interpretation problem from my perspective.

You can demonstrate how to obtain an average power out of the superposition
of two waves that is greater than the sum of the power components of the
original two waves????? Steve, think about what you are saying. You are
saying that you can create energy. Do you really consider yourself to be
an omnipotent being?

> Presume the two orthogonal waves that intersect are of equal amplitude and
> 180 degrees out of phase.

When you say "orthogonal waves", does that mean the waves are orthogonal
to each other or that the E and H fields are orthogonal?

> My interpretation is that the waves cancel (at
> the point of intersection) and that the net energy extracted from the
> resulting wave as a function of time is 0 (at the point of intersection).

The waves indeed do cancel, Steve. But it is impossible for the energy in
the waves to go to zero. When waves cancel, the energy goes to zero IN THE
DIRECTION THAT THE WAVES WERE TRAVELING. That same energy simply reverses
direction and goes the other way, i.e. it is reflected. READ MY LIPS!
ENERGY CANNOT BE CANCELED!!! If energy appears to be canceled in a transmission
line, it has simply reversed direction, i.e. been reflected. There is no
black hole inside a transmission line.

> The waves are still there (they do continue on there way after they
> intersect) but no net energy as a function of time is being extracted from
> the waves (at the point of intersection). Your interpretation of the
> problem requires the "canceled energy" to go somewhere. Where does it go
> and how can I measure where it goes?

I have explained that to you a couple of dozen times over the past year and
a half but you simply don't listen. The canceled energy is exactly the energy
in your term 2 Sqrt(P1) Sqrt(P2). That energy does NOT originate in P1 and P2
at all. 2 Sqrt(P1) Sqrt(P2) is obviously constructive interference energy. I
think you will agree with that statement. Constructive interference energy is
NOT free. It must be accompanied by destructive interference. The destructive
interference is from your wave cancellation process. If you can measure your
term, 2 Sqrt(P1) Sqrt(P2), you will be measuring the energy in the canceled
waves. It *is* the constructive interference.

Your 2 Sqrt(P1) Sqrt(P2) constructive interference energy is re-reflected
energy from the wave cancellation (destructive interference) process on the
other side of the match point. Did you really expect to hide that fact
forever?

Cecil:

QSL.net could be just another one of those "dot-com" businesses gone bust.
Too bad, but then... I was wondering when that would happen. If you ever
looked at all those useless web sites on their servers taking up disk space
and
bandwidth for no good return.

The whole "dot-com" economic mess reminds of the comedian who told the
story about the used car salesman who's "come on" line was, "You ask how
I can keep selling all these cars below cost? Well, I'll tell you my
friends. It's
volume, volume, volume!"

Heh, heh...

Same with all those communications companies selling huge excess
bandwidth overbuilt with Venture Capitalist's mone, to each other
and then booking the "future minutes" as revenue! Wow, what a way
to run a railroad.

BTW... $15 is not a lot of money to run a web site for a year!

Businesses with red bottom lines all go under eventually.

I wondered what "the ultimate Plan" for QSL.net was anyway, they didn't seem
to have any Vulture Capitalist money to spirit away into Swiss bank accounts
and Boca Raton mansions. Like the Worldcom, Global Crossing, et all...
What is/was their plan anyway?

I just got a Palomar Loop Amplifier and Palomar Loop Antenna for 160/80 meters. I'd like to wind antennas for BCB, VLF, and maybe other bands. I wonder if anyone has wound any loopsticks for this box with any success. Looks like there's a 2N2222, and 2 MPF 102 in the amp. Any help with a schematic or antenna info appreciated.
tnx

Steve, VE9SRB wrote:
"Presume the two orthogonal waves that intersect are of equal amplitude and 180 degrees out of phase. My interpretation is that the waves cancel---."

If the lead / lag of the waves are the same, their volts and amps, or E and H fields, cancel at the point of intersection. But, I don`t see any direct relevance with forward and reflected waves on a transmission line.

Whatever net volts appear at the input to a transmission line, the result is an in-phase forward current on the line.

The forward wave may be bounced by an impedance bump to some extent. The reflection from the impedance bump has an inversion in the phase of either its volts or amps, depending on the direction, load too low or load too high, but only the volts or amps are inverted, not both. So, the reflected wave presents volts which are 180 degrees out of phase with its amps. This will propagate back toward the sender with the reflected current locked in this 180-degree phase relationship with the reflected volts on the transmission line.

SWR diagrams show a displacement of 90 degrees between volts and amps, but this is only due to interaction between waves traveling in opposite directions.

So, any place on a transmission line, there are only in-phase and out-of-phase voltages and currents to work with when considering how you add the powers in the individual waves. There are no orthogonal waves intersecting on a transmission line of significant length.

Let's do a mental experiment to see if you are correct. The source
is a star 20 light years away. We have engineered two coherent light
waves traveling side-by-side using the light from that star. Now we
divert those two light waves such that they interfere with each other.
You are saying that the source star, 20 light years away, recognizes
the problem and increases its energy output to compensate for the
constructive interference we see between those two waves. Steve, even
if you are right about that somewhat unusual source star increasing its
energy output, it will take 20 years for the star to know it should
increase its energy output and another 20 years for the increased energy
to have any effect on our experiment. During that 40 years of response
time from your magic star source, where does the energy in the constructive
interference come from?

Is this starting to soak in for anyone? It apparently has not started
to soak in for Dr. Best.

Hank:

I developed a similar design that was published in 73 Magazine in
three parts in the July, August and September 2002 issues.

The articles cover loop design down to 21 KHz, in a combination of
air-core and ferrite core antennas.

If you don't have access to 73 Magazine, drop me an e-mail.

Yeah, it makes me think the guy who wrote it was a fear-monger. Stay tuned to the upcoming Supreme Court decision upholding the second amendment, and the outrage it will engender among the advocates of gun control.

Does anyone know anything about MFJ's apartment antenna? It says it attaches to window sills and covers 10m to 40m plus 2 and 6 meters by changing coils. What it doesn't tell you is what kind of gain this thing has and what kind of pattern it has. Does anyone have this antenna or know how good it works? KA9MAT Barry

Why not just build one per the directions in the ARRL antenna book?

OR just go down to Radio Shack and buy their discone.

If you are looking for a 2m antenna only save some money and frustration and
build yourself a j-pole or 1/4 wave vertical. They can be made for next to
nothing and will work as good or better than the MFJ gear. And no ground
needed either.

Barry,
Off hand I'd say the thing had no gain and
the radiation pattern depends a bunch on how
and where you have it mounted. For 2 meters
you should think of it as a step up from a
rubber-duck, and not quite equal to a 'real'
antenna of almost any kind.

Hi All:

Just a comment, I don't think that they use copper weld. I don't think the steel core would last too long buried in the ground. From a performance point of view, insulator or not insulated doesn't make any difference.
I have been looking at a 80/40m vertical at my QTH, and in the interest of getting the most bang for the sweat, I've been modeling the gain of a vertical verses the number and length of the ground radials. I find it interesting that for 32 radials the length that gives the maximum gain is 40 feet, but for 120 radials the max gain occurs with a length of 65 feet on 80m. As a note the angle of max radiation is the same for either number of radials.
I believe a way to explain this is there is an optimal "density" of radials and for each number of radials there is a length that gives that density. Of course I could be seeing some short coming of my modeling software too.

Makes no difference. The steel coulld completely disappear (unlikely). The r-f skin depth in copper (a few thousandths of an inch) is less than the copper thickness and copper lasts. In the soil, the steel core is less needed for strength.

Best regards, Richard Harrison, KB5WZI

Not anonymous, I just started a new NG topic named "Reflected Pwr at Tx" so the subject wouldn't be buried and nearly invisible in this wandering thread. I emailed Richard Harrison to be sure he noted it.

Here is a paste of my original post, and my latest under that subject line:

ORIGINAL

If (as stated below), no reflected current or voltage is seen by a transmitter, please tell us the reason why transmitter output stages can arc and smoke when reflected power is too high? That won't happen if the only dissipation ever seen by the tx output stage is due to its DC-RF conversion efficiency.

This is far from an academic concern.

I guarantee that you cannot demonstrate what you think you are
demonstrating. With a fixed output power from the source, you
cannot demonstrate constructive interference without an equal
magnitude destructive interference.

> I'm trying to think of a similar experiment with light - I'll let
> you know if I can come up with something.

OK, here it is. According to your theory, non-glare glass doesn't
cause destructive interference of light and when one brings a piece
of non-glare glass into the room, the light bulb in the room increases
its power output. You said exactly that in the following:

> The total forward power increases as a direct result of the vector
> superposition of forward voltage and current. This DOES NOT require a
> corresponding destructive interference process (reduction of power
> elsewhere) to balance the law of conservation of power (The power
> dissipation in the source increases at the same time the forward power
> increases - it does not need to correspondingly decrease).

So show us that magic light bulb that increases its output power
every time it somehow detects a piece of non-glare glass in the room.

I was aware of those sentiments from the statements posted on the Web Site
and I am indeed sorry and do apologize if my remarks seemed to indicate
that I felt the QSL.Net Web Site is/was some kind of scam.

Cleary it was/is not.

That being said, running a Web site is not inexpensive in terms of time,
effort and financial considerations. All such efforts whether inspired by
egalitarian principles or not must evenutally pay heed to sound business
principles. i.e. the captital and operational costs have to be covered
somehow or the service will eventually degrade.

I for one hope they do well.

However my observations of the large number of relatively useless Web sites
which have been set up, and the poor real time performance of the servers,
at the QSK.Net URL lead me to believe that they might not be in the best of
shape.

RE: Below

"Some people" = me, no doubt.

Probably everyone (including me) agrees with your last sentence below.
However this does not necessarily mean that the power it displays is highly
accurate, and/or independent of its operating conditions.

I am not attributing any characteristic to this meter not based on its true,
but sometimes unrecognized performance in typical applications -- and
writing about one used when greater accuracy is required.

I think the question that Richard is asking is: If all the reflected
power is re-reflected at the transmitter whether there is an impedance
match or not, then why do the transmitter designers include protection
circuitry to protect the finals from over-voltage and over-current.

If a final designed for 100V max into a 50 ohm load is forced to deal
with 200V caused by reflections, it is likely to arc (punch through).
If a final designed for 2A max into a 50 ohm load is forced to deal
with 4A caused by reflections, it is likely to overheat. Please don't
tell me the designers are protecting the transmitter from virtual
impedances, i.e. shadow boxing.

A virtual impedance has absolutely no effect unless it is physically
supported by a real impedance discontinuity. Please describe in detail
the impedance discontinuity in a transmitter. (I don't know the answer
but I do know that virtual impedances are effects rather than causes.)

I'm looking for some inexpensive 1/4 wave magmount antennas for a VHF freq (151 MHz). I'll even consider a cheap mount-only that I can add a whip to.

Anyone know of any surplus outlets with anything? Anyone online selling something like this? Anyone ever cut down one of the dual-band antennas that I occasionally see for $15?

I'm looking for about 10-15 of these and am trying to keep cost down as its coming out of my own pocket. These antennas will be seeing fairly light duty as part of a crime watch group's short range comms.

TIA,

Bob

Bird claims 5% of full scale if and only if the wattmeter is operated
in a 50 ohm environment (for a 50 ohm slug). 5% of full-scale is 20%
of quarter-scale and it is still operating within specifications. Most
of us don't care much about accuracy - just that the needle doesn't move
when measuring reflected power.

Antennawarehouse.com sells an OK discone for $29. I am using one right
now and it works just fine.

The only reason to pay $30 more for the Radio Shack is if you want to
TX on 6M and don't want multiple antennas.

5207. Simple horizontal antenna advice III

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-22 15:34:21 UTC

Source record: 128595

Hi,

I thought I'd post a followup to my previous posts.

To summise, I constructed a 120 feet doublet fed by 600 ohm open feeder. Because of the shacks location the feeder dropped from the feedpoint and then rose to enter the shack. The feeder ran parallel to one leg of the doublet and at the shack entry point is only a couple of feet from the doublet. With this config I was having issues getting the antenna to tune up.

I've since extended the length of the openfeeder and trailed it away from the doublet, it now entering the shack from an opposite direction. This addressed a lot of the problems and it tuned up alot better but I still wasn't entirely happy with it.

I was using the voltage balun integral in my MFJ-949E tuner. Reading various references a current based choke balun seemed a better choice. A simple 1:1 choke was contructed out of 25 feet of RG58 coiled onto a 4 inch drain pipe. The result is the antenna tuning is now alot less peaky and performance, certainly on receive, seems unchanged from the internal balun.

Thanks for the groups advice over the past few weeks. I look forward to experimenting some more over the coming months.

73 Steve M3ZQO.

5208. Reflected Pwr at Tx Followup

(I had to start a new thread because of the delay I get using
Google to read and post right now - my ISP's NG server is kaput.)

Here is a repeatable example from my working life supporting the
presence of discrete, reflected (reverse) power in the output stage
of a transmitter, as opposed to those reflected/reverse waves merely
changing the loading conditions for forward power from that tx,
as suggested by Richard Harrison.

FM broadcast stations sometimes co-locate their transmit antennas
on the same tower. In some cases these antennas are physically
close enough that significant RF power couples from each antenna
to the other. Let's consider a case where the two carriers F1 & F2
are 0.8MHz apart, and further that each station produces a signal
in the transmission line of the other station that is 20dB below
that station's unmodulated carrier level (distinctly possible).

Absent any kind of spectral filtering, F2's signal will travel down
the line and appear in the output network of F1's transmitter. Even
with the F1 tx turned off, F1's reflected power meter will respond
to the interfering signal from F2 as if it was a reflection of power
generated within the F1 transmitter. In this case it would read a
power level equal to that from a load Z with a return loss of 20dB,
which corresponds to a 1.22VSWR.

If F1 transmitter is now turned on, F1's spectral components will mix
with the interfering signal from F2 to create RF intermodulation
products, the most dominant of which is produced by the 2nd harmonic
of F1 mixing with thefundamental of the F2 interfering tx 2F1-F2).

A similar scenario will exist at the F2 transmitter with F1 as the
interfering source.

If reverse power did not appear as a discrete value in the output
of the PA stage along with the forward power the PA is generating,
then RF intermods would not be produced in this situation.

But they are, ergo...

>Yeah, it makes me think the guy who wrote it was a fear-monger.<

No hyphen in fear monger, Tom, it's a noun. The hyphen may be used when the term serves as a modifier--as in "fear-mongering red-neck moon-shine sucking sister-chasing rodent brain". Come to think of it, isn't a "fear monger" the conservative counterpart of a "northern anti-gun panty-baby bed-wetting liberal control-freak wuss?"

Back in college debate, I recall that name-calling resided at the bottom of the rhetorical food chain--somewhere below personal attack. It represented the very weakest position available from which to post an argument--and it always reeked with the stench of defeat. Too bad it's been raised to an art form in our post-modernist era.

Yes, that's what I would like to know. In the past I used electical
house wiring for this, which by default is insulated. Sometimes I
removed the insulation mostly I did not. I thought maybe someone out
there had some more practical expriences on the differences between
both possibilities.

"OC_CAM's Razor" <Cecil.A.Moore@ieee.org> wrote:
> Most of us don't care much about accuracy - just that the
>(inline wattmeter) needle doesn't move when measuring
>reflected power.

However a "Bird-type" wattmeter reading zero reflected power should be viewed with due care, because *true* reflected power will be far from zero
then.

The meter just reads zero because the magnitude and phase of the forward
power in the sample section exactly nulls the true reverse power there coming back from the load termination. This is the result of the finite
directivity of the element, which does not completely isolate forward from reverse power.

And a "Bird-type" meter looking for reverse power into a perfect, resistive
match will not read zero watts, even though reverse power really is zero.
The reason is the same as above.

Note I am not bashing this approach, just suggesting it be used with an
understanding of how it really performs.

It would seem that practically any 2-meter 1/4 wave whip would work. Shorten it another inch or so for 151 mhz. Or, just buy a bunch of mag mounts, and insert your own approx. 18- or 19-inch whip wires.

You might look at hamstick.com They have 1/4 wave whips at $7.95, mag mounts at $12.95...

It is a base loaded antenna and is slightly shorter than a mobile
Hamstick. So, It's performance at frequencies lower than 10 meters would
be similar to a small base loaded mobile whip.

Very poor on 40, poor on 30, fairly poor on 20 and 17, fair on 10, good
on 6. However, even on 6 meters it is not as good as a 1/4 wave ground
plane.

It works, but you could do better!

Yes, and more than the 50-ohm slug calibration is involved. The 4-inch
length of coax line in the Model 43 wattmeter has a Zo of 50 ohms, too.

Bird doesn`t claim laboratory accuracy. They do make lab instruments
too, but the field instruments do what they are claimed to do very well.

One technician can adjust a radio for a particular power output. Then,
another technician using a different but similar Bird same model
wattmeter can check the radio. Chances are excellent that the readings
made by the two technicians will agree. I`ve seen this happen countless
times. In my organization, this repeatability was more important than
accuracy. The radios traveled all over the world and were serviced and
reported from far-flung locations. The repeatability was there.

Best regards, Richard Harrison, KB5WZI

I'll stand to be updated since it's been 40+ years since I took my transmission line courses.

I understand the following:

The transmitter output circuits, inductors and capacitors, provide a match between the transistors and a 50 ohm source impedance to the transmission line. The transmission line has a 50 ohm characteristic impedance [assume no losses]. The load [antenna] impedance is assumed to be 150 ohms [VSWR 3:1 Reflected power 25% or 25 watts for a 100 watt transmitter].

The reflected power, 25 watts, comes back down the transmission line which has a 50 ohm characteristic impedance. The transmission line is terminated by the output circuits of the transmitter circuits which are design for 50 ohms. The output circuits of the transmitter are linear components [inductors and capacitors] that exhibit duality and provide a match between the transistors and the transmission line. This is a 1:1 VSWR! There is NO reflection of the reverse traveling wave. The wave [power] reflected from the antenna sees a 50 ohm load at the output of the transmitter. The power is coupled back into the RF Final stages.

So, if I have a transmitter that provides a 50 ohm load to the reflected wave and a 50 ohm source impedance to the forward wave, and I have a 3:1 VSWR at the antenna, is not the 25% reflected power absorbed by the transmitter??? Hmmm ... ???

Richard, you are correct in identifying that intermod products occur.
This gives evidence of the reflected power being coupled into the
non-linear stages.

Just one point of clarification though for completeness. The mixing
process, 2F1 +/- F2, also has a conversion efficiency where in the
mixing products are less than [lower valued] the individual components.

SHALLOW-BURIED RADIAL SYSTEMS.

The RF effect of covering wires with an insulating material is to REDUCE the input (loss) resistance of the array. The greater the diameter of the insulation over the wire the lower the loss.

For practical purposes all loss occurs in the soil and for short distances current flows radially outwards from the wire surface.

By far the greatest amount of loss occurs in the layers of soil in contact with and immediately surrounding a wire. That's where the transverse resistance of a thin layer of soil is greatest and where the greatest current concentration occurs.

Now suppose a wire is replaced by a polyethylene-insulated inner conductor of a coaxial transmission line. Insofar as the soil is concerned the radial wire now has a much greater diameter. Suppose it's 1" in diameter. The cross-sectional area of the soil involved is much greater and the current density is much smaller. So the effective loss resistance must be smaller.

But depending on the permittivity of the insulating material there is now a capacitance between wire and soil. It is exactly the same capacitance as existed in the original coaxial line before the outer conductor was removed. So the input impedance of the radial array consists of a LOWER LOSS resistance in series with a capacitative reactance.

No-one is aware of the change in input reactance because it is tuned out simultaneously with antenna reactance with which it is in series.

The whole thing is calculable from its dimensions. Does the ARRL Bible or Terman have anything to say on the subject? ;o)

[PS. It follows that to reduce loss in a radial system to an absolute minimum the best course of action is to insulate the wires with a very large thickness of air. This is accomplished by taking them right out of the ground and raising them to a height of about 1/2-wavelength. Has this brilliant flash of inspiration yet been patented?]

<Cecil.A.Moore@ieee.org> wrote:

>"Conservation of Power" is in the index.

Hi Cecil,

Now there's a recommendation. Is it too baroque to quote?

If you want to talk Physics, go to a Physicist, not a derivate.

From Feynman's Lectures, "conservation of energy":
"There was an interesting early relationship between
physics and biology in which biology helped physics in
the discovery of the conservation of energy, which
was first demonstrated buy Mayer in connection
with the amount of heat taken in and given out
by a living creature."

Thus introduces the notion of an event (taking one amount), over time
(in and out) and accounting for any gain or loss found in the amount
at the end of the event. But Feynman goes on:
"There is a fact, or if you wish, a law, governing natural
phenomena that are known to date, There is no known
exception to this law - it is exact so far as we know.
The law is called the conservation of energy. ...
It is not a description of a mechanism, or anything concrete;
it is just a strange fact that we can calculate some number
and when we finish watching nature go through her tricks
and calculate the number again, it is the same."

Only Feynman could make this snobbery of conservation into a cosmic
joke. Conservation... explains nothing. As for the mental abacus
I've seen employing Conservation, too often inappropriately,
Interference is not one shot frozen in time at some precise
intersection of two one dimensional lines. Not even in the pristine
world of math/science/religion/economics/politics/ebonics.

Cecil, the point of the matter is that when you've halted the
discussion to line up your argument, halfway through the event, I am
satisfied to find Conservation AFTER, as Feynman says, "watching
nature go through her tricks."

Agreed. The conventional term used in the broadcast industry is "turnaround loss," which is defined as the difference between the amplitude of the primary interfering signal and the intermod product(s) observed as a result of its presence.

Note that the IM product 2F1 + F2 lies well outside the RF bandwidth of the F1 tx and antenna, typically, and so the turnaround loss for that product usually is quite high, and its interference potential quite low (near zero).

RE: Below

Agreed. The conventional term used in the broadcast industry is "turnaround loss," which is defined as the difference between the amplitude of the primary interfering signal and the intermod product(s) observed as a result of its presence.

Note that the IM product 2F1 + F2 lies well outside the RF bandwidth of the F1 tx and antenna, typically, and so the turnaround loss for that product usually is quite high, and its interference potential quite low (near zero).

> --

if you define a 'point' as your closed system it has no dimensions,
therefore no way to store energy, so yes, joules in equals joules out over
any time period you want to define. however on a finite size object you can
put more joules in during a given time period than you take out. just
consider a simple capacitor or inductor, both of them can store energy for a
time so you could pump in joules and not get any out. we have a device at
work that you pump in a kw for say 5 minutes and get nothing out, then you
get a few megawatts for a microsecond or so... that would hardly pass muster
with your definition of the 'law'.

In checking my standard references here, Jackson's Classical
Electrodynamics, Ramo/Whinnery/VanDuzer's Fields and waves in communication
electronics, and Desoer/Kuh's Basic Circuit Theory the only reference to
conservation of power was in Basic Circuit Theory where it is defined as the
'conservation of complex power' which relates specifically to a linear
time-invarient network in sinusoidal steady state. in such a case you can
show that the complex power is conserved. unfortunately it is based on
Tellegen's theorem that is valid only for lumped networks. this would lead
me to believe that unless you used the lumped ladder type model for a feed
line that you can not directly apply a 'conservation of power' law to any
piece of the network, you have to include the whole thing from the
transmitter through the antenna. THEN, it makes sense, in steady state the
power from a transmitter is either radiated or heats the coax, and the sum
of the radiated power and the power that is transformed to heat equals the
power coming out of the transmitter.... no big deal in that.

now, there is something to sink your teeth into. BUT, you still have to be careful to define the system you are looking at when you apply the 'conservation of energy' law. i am still astounded at how many people get the answer to the following question wrong:

You put a refrigerator in a perfectly insulating room and open the door. (assume the light is burned out so that doesn't heat the room up) What happens to the temperature in the room? Does it go up, stay the same, or cool off?

another new term for me... what in the world is a 'virtual impedance'?? is
this an impedance modeled in a computer that doesn't really exist? how does
it relate to a real or complex impedance? is power conservered in virtual
impedances???

Arie wrote:
"Yes, that`s what I would like to know (that the insulated wire he used for ground radials was just fine)."

Insulated wire does not provide the lowest resistance to earth. It doesn`t provide the lowest reactance, either. An insulated wire doesn`t make the best capacitor plate because when it is fed from an end it has inductance which works against its effectiveness as a capacitor plate. Inductance can be reduced by using enough insulated radials to reduce total inductance, and to increase total capacitance.

Bare wires make better ground radials. Elevated radials, or the radiator itself, can be insulated with little effect on their performance. Enough elevated radials are needed to hide the earth from capacitive coupling with the radiator. That takes many radials near the earth, or just a few at high altitude.

Best regards, Richard Harrison, KB5WZI

> satisfied to find Conservation AFTER, as Feynman says, "watching
> nature go through her tricks."

What seems really strange, Richard, is that you hold me to such a high standard but refuse to hold Dr. Best to any standard at all. One wonders why. Do you agree with Dr. Best that if we cause constructive interference between two coherent waves consisting of light from a star 20 light years away, that the star immediately increases its power output to compensate for the constructive interference so destructive interference is avoided at all costs - even at the cost of violating the theory of relativity AND the conservation of energy principle.

Do you really believe that when I walk into a room with my non-glare eyeglasses on that the light source in the room senses the presence of my non-glare eyeglasses and increases its power output so that destructive interference can be avoided at all costs? That's what Dr. Best believes as can be ascertained from his assertions:

Dr. Best wrote:
> The total forward power increases as a direct result of the vector

Of course, but aren't those joules conserved even if they make
it to the load after the transmitter is powered down? One of my
favorite examples is a one second long transmission line. The
transmitter dumps 100 watts of power into the line. The line contains
energy equal to the first second's worth of that 100 joules/sec
until the transmitter is powered down. The transmitter is generating
power (by definition) and the transmission line is storing that
dynamic power as equivalent dynamic energy. Power and energy in a
lossless transmission line are equivalent and related only by time,
i.e. the power in a lossless transmission line is not used up.
And anyone who thinks the charge on a capacitor cannot deliver power
should grab a 100uf cap with 1000V stored in it. We can't feel vars,
can we? :-)

"This is far from an academic concern."

The transmitter`s open-circuit voltage is likely more than its normal loaded voltage.

The transmitter`s short-circuited current is likely more than its normal loaded current.

A seriously mismatched transmitter may be vulnerable without recycling its power output.

Transistors being less accommodating in their earliest high power applications than vacuum tubes were and often still are protected from overload by additional circuitry.

Does anyone have evidence showing recycled load power did in his transmitter and that it was not voltage or current overload caused by a severe departure from the design load impedance?

Egads, David, have you never heard of virtual images? The 50 ohms seen by
the transmitter in the following diagram is a virtual 50 ohms. The actual
50 ohms is at the other end of the ladder-line.

50 ohm XMTR--+====1/2WL 450 ohm ladder-line===50 ohm resistor.

Please don't tell me that you have been seduced by the steady-state model
and think the transmitter actually sees a 50 ohm resistor.

no, power and energy are not the same in a lossless line. consider your 1
second long line. at the input end 1/2 second after the transmitter is
turned on you are putting in 100w, but nothing is coming out the far end...
hardly a good example of conservation of power... and yet if you properly
define the system boundaries you can calculate that energy is conserved.
conservation of power as defined in my books only works in 'sinusoidal
steady state' in a lumped network, and even then you have to use complex
powers. you can not apply those assumptions to your long transmission line
and a transient phenomenon.

5243. Inline Wattmeter Accuracy

OC_CAM's Razor" <Cecil.A.Moore@ieee.org> wrote
> Are you saying that a 50 ohm load fed by a 50 ohm coax will not
> indicate zero reflected power?

True reflected power is zero for those conditions, but an inline wattmeter will not read zero then. It will read whatever power its element can't reject from the forward power in the line.

With ZERO true reflected power, an inline wattmeter element with its typical directivity spec of 26dB will read about 5 watts of reflected power for every 100 watts of forward power.

> Or are you saying there's no such
> thing as a perfect 50 ohm load fed by a perfect 50 ohm coax
> measured by a perfect 50 ohm wattmeter?

Transmission lines and terminations can be constructed or matched to high return losses (70dB or more), at least over limited RF bandwidths. With careful design and custom calibration, directional couplers also can approach this performance, as well.

However most standard, commercial transmission lines and reference mismatches/loads have better off-the-shelf performance than the off-the-shelf directional couplers/wattmeters we are discussing.

An additional consideration is that the directional coupler should have at least 10dB better directivity than the return loss performance of the load it is used to measure. Therefore if the true VSWR of a termination is 1.03:1 (36dB return loss), the directional coupler needs 46dB directivity to measure it with tolerable(?) error. That is 20dB beyond the spec of the typical inline wattmeter element.

Richard Fry

given that you are in steady state and the line is lossless with a 50 ohm
resistor on the far end you can not tell the difference between what you
have drawn and a 50 ohm resistor hooked to the transmitter. nothing virtual
about that.

what are you calling 'virtual'??? the input impedance of a transmission line
with some load? those are hardly 'virtual'. given the characteristics of
the line and the load impedance you can calculate a very real impedance that
the transmitter will see in the steady state case. and given a steady state
case you can replace the line and load with a single impedance connected
directly to the transmitter and you would not be able to tell the
difference. if you want to talk transients it is a very different problem.

Seems to be a multiple choice question:

If the refrigerator was plugged in before and not plugged in after
being put in the room, and the room is at room temperature, the
temperature would fall.

If the refrigerator wasn't plugged in before and not plugged in
after being put in the room, it would depend on the temperature
of the refrigerator Vs the temperature of the room. It could go
up or down.

If the refrigerator wasn't plugged in before and then plugged in
after being put in the room, the temperature would rise assuming
the room was previously at room temperature.

If the refrigerator was plugged in before and after being put in
the room, the temperature would first fall then rise, assuming
the room was at room temperature and it's not a gas refrigerator.

If the room was already at the melting point of steel, the
refrigerator will probably malfunction as it has an upper
temperature spec.

If the room was at absolute zero, the refrigerator will probably
malfunction as it has a lower temperature spec.

Remember the "Fair Witness" from "Stranger in a Strange Land"? :-)

c-, incomplete answer. assuming the heatsink side of the mechanism was
still warm that counteracts the cold air inside. what happens after the
transient due to opening the door has decayed away.

Hi,

some time ago, started to do solve my antenna problem,
living in a block is boring ... Can do anything on my
balcony ...

I made a long search on the net, books and magazines. Any
new article made me more confuse. To avoid more of this and
finally to be QRV or SWL, I need help from you.

a) Resuming to install a 1/4 dipole on the balcony, how away
should the dipole placed ? Since some manuals telling, that
a dipole can be installed indoors, may be the distance
between the dip. and wall is not so critical, or not?

b) Many people and web sites favoring mag.loop antennas. How
fine they are, effective ... Sure very small bandwidth.

If you should choose, which one you would prefer on your
balcony, the dipole or the mag. loop? (for 10 meters).

c) Last week found a web site about so called "microvert"
antennas. (http://home.t-online.de/home/dl7pe/mainmenu.htm).
Read also opinions, all positive, from hams, who build this one.

So, if you had to choose;-)

- a dipole at the balcony
- hide the dipole on the roof
- take the mag. dipole on the balcony
- take the mag.loop to the roof
- build your microvert and use it on the roof

what would you say?

Oh no, you *have* been seduced by the steady-state model. You think the
image of yourself that you see in the mirror is really your twin brother
living in the room behind the mirror?

Assume you are a wave, David, and flow toward that junction. Do you see
50 ohms? Do you detect a temperature rise? Of course not! All you see is the
lossless interaction of individual forward and reflected waves like yourself.
There is NO power dissipation at the virtual resistor and it doesn't get hot.
That's the difference that proves the resistor is not really there and is only
virtual. You say I cannot tell the difference - I certainly can by taking the
temperature.

You can prove that there is not actually 50 ohms at that point. Put a bit
of high frequency modulation on the wave that changes from cycle to cycle
and you will not see a perfectly continuous 50 ohms. You will actually
see some small reflections incident upon the transmitter. If you really
want to see the effects, use a 1000 ft. piece of ladder-line and make the
load a 75 ohm TV receiver. You will see ghosting all over the place.

If the refrigerator had just been shipped in from the South Pole,
the heatsink side would be cold and if you didn't plug it in,
the temperature in the room would drop. :-)

We've had this discussion. I had thought that you were cured - in your subsequent postings you *properly* invoked the principle of 'Conservation of Energy'; now you're slipping back.

'Conservation of Power' is not a general 'principle'. That book is wrong if it says that it is a 'principle'. Dangerous misinformation - you should 'red-line' your copy at the very least.

> Have you ever seen the joules passing a
> point in one second not be conserved?

Depends on the situation Ever seen a Pulse Compression Radar ? That is a crystal clear and classic example where power gets 'stacked up' into a narrow pulse. Energy is conserved of course - power isn't. There are a million examples.

Of course I'll be happy to grant you that power is usually conserved in transmission lines provided nothing funny (like reflections) is going on. Just don't invoke the non-existent 'Law of Conservation of Power' to prove that power is conserved. That would be circular reasoning (and based on a false premise in any case).

..

Good luck with your debate. I'm still trying to pin-point where either one you has gone wrong in your logic. I suspect it is related to your differing assumptions about the reaction of the so-called "100w" transmitter (no such thing actually) and its reaction to the mismatch.

I can paint you a mental picture. Assume an open circuit, one second long
lossless 50 ohm transmission line. The transmitter is perfectly happy for
two seconds and then starts to suffer. Sounds like reflected power damage
to me.

ah, but i have one advantage. i know when to apply the steady state

approximations and use the conclusions they give, and you obviously don't. i specifically stated that in the steady state you could not tell the difference between 50 ohms at the end of a 1/2 wave line and 50 ohms at the transmitter terminals. you have just said that if i change the wave cycle by cycle i can see the difference. and i say, of course you can, but you just violated my statement that declared 'steady state'. the same applies to tv signals, because the modulation changes so rapidly they can never be assumed to be in steady state.

now, as far as taking the temperature... if i put the 1/2 wave of line in a box along with the 50 ohm resistor and let you measure that temperature... then take out the line and just put the resistor in the box and let you measure that temperature they would be the same and you still couldn't tell the difference, in steady state. this is where the refrigerator question comes in to play, if you are going to reduce a network down to an equivalent impedance you must be sure to include all the applicable parts of the network. in this case the resisitor that creates what you call a 'virtual' impedance is a part of the network and must be included or you will not be able to satisfy the law of conservation of energy. so my statement stands, in steady state i can give you two boxes, one with only a 50 ohm resistor, and one with 1/2 wavelength of lossless line and a 50 ohm resistor, and you could not make any measurement that would tell them apart.

as far as the mirror analogy, there are ways to do the same analysis for light waves and mirrors, but they require the same type of analysis as lower frequency waves in a coax with a mismatched load. after all they are just E-M waves and follow the same rules.

Yes, you have the advantage of the old dead horse steady-state strawman cop-out. The only thing I can detect is change and you say if I change anything it is not steady-state. Congratulations on your Catch-22, a rule that prohibits the questioning of that very rule.

> in this case the resisitor that creates what you call a 'virtual'
> impedance is a part of the network and must be included or you will not be
> able to satisfy the law of conservation of energy.

But you are not allowed to have your energy and eat it too. If it gets dissipated in the load resistor 1/2WL away, it doesn't get dissipated in the virtual 50 ohms at the transmitter, i.e. there is not 50 ohms at the transmitter. There is only a complex interaction of forward and reflected waves that nobody except me seems to understand. (That is a tongue-in-cheek statement, in case anyone objects.) The only resemblance to an actual 50 ohms is the V/I ratio which, like a lossless Z0, is dissipationless.

Please see my posting, "Riding the Waves".

The fact that you're continuing to wave it about like some flag demonstrates that you need to review Physics 101. Seriously, and with all due respect, you should know better.

It only takes a single counter example to blow a so-called 'principle' out of the water. *Pulse Compression Radar*. Done. Men of Few Words Champion.

One last time:
1) There is no such thing as a 'Conservation of Power' principle. There is, occasionally, given some assumptions, situations where power is conserved. Doesn't make it a principle.

2) If Walter C. Johnson says there is such a principle, then he is dead wrong.

3) Please stop quoting him as some sort of God-given reference.

4) 'Appeal to Authority' arguments are lousy even if the expert isn't wrong.

5) Circular arguments are even worse.

6) Appealing to a non-existent principle is... sigh...

I'm getting bored with this. Next time someone mentions 'Conservation of Power' as being some sort of fundamental principle, I'll try to smirk more quietly.

If the refrigerator is plugged into a source of energy the temperature goes up.

The compressor is inefficient and has thermal losses. So, it takes more BTUs to operate the compressor than the resulting BTUs reduction from the compressor output. A simpler model is to run an air conditioner totally inside a closed room. It gets HOT.

If the refrigerator is thermally stabilized and not operating then the temperature remains the same.

There is NO PERPETUAL NOTION MACHINE !! Nothing runs at 100% efficiency! So, losses, generally as heat, occur in all processes.

Another way to understand the process. A 100 horsepower automobile engine can deliver about 35 horsepower to the road! Most of that missing horsepower is converted into heat in the exhaust [caution: just put your hand somewhere near your catalytic converter and you will feel quite a bit of heat!], in the engine oils, in the coolants, in the brake pads, in the tires. Note: the tires are flywheels that take an exceptional amount of power just to rotate. The crankshaft takes power to rotate, transmission fluids get VERY hot, etc.

The amount of energy, not power, in our COSMOS is fixed and constant. It was there at the instant of the BIG BANG. All we can do is change the type of energy and measure how quickly energy is consumed in any local engine [read transmitter]. My ICOM 746 requires somewhere around 250 watts input to produce 100 watts output.

5262. Riding the Waves

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-22 22:48:55 UTC
From: OC_CAM's Razor <Cecil.A.Moore@ieee.org>
Message-ID: <3E064157.8010203@ieee.org>
Source record: 128651

Einstein envisioned himself riding waves of light on his way to his theory of relativity. It's a very useful concept. When one rides the crest of a wave traveling at the speed of light, one has all the time in the world to think about it since one's wristwatch is not ticking at all. Let's ride the forward wave from the transmitter to the load in the following example and see for ourselves what happens.

100W 50 ohm XMTR--coax--+===1/2WL 450 ohm ladder-line===50 ohm resistor

We emerge from the XMTR riding the wave in a 50 ohm environment. Our wave is 70.7V at 1.414A in phase. We might be headed for a 50 ohm load. But we look ahead and see an impedance discontinuity. It is a step function from our 50 ohm environment to a 450 ohm environment. We are pretty savvy about such things and brace ourselves for a reflection of 64% of our power. We sure don't see 50 ohms. What we see is a bunch of interacting waves.

SWR = 450/50 = 9:1, Rho = (SWR-1)/(SWR+1) = 0.8, Rho^2=0.64 or 64%

As we get closer to the impedance discontinuity, we realize that we have already achieved steady-state conditions and a large destructive interference process is in progress which tells us there is an impedance match happening at the impedance discontinuity. Assuming that our wave arrives at the impedance discontinuity with the V-I phase angles at zero degrees, we know the discontinuity will generate a reflected wave of 56.57V at zero degrees and 1.13A at 180 degrees. But we do not see such a wave flowing back toward us. As we get closer we see why. There is a reflected wave from the load flowing through the impedance discontinuity and its voltage is 56.57V at 180 degrees and its current is 1.13A at zero degrees.

Of course, now we realize what is happening. We're smarter than the average bear and know that coherent waves with equal voltages and currents and opposite phases will cancel each other. That's why it's so dark on this side of the impedance discontinuity.

56.57V at 0 degrees and 1.13A at 180 degrees added to
56.57V at 180 degrees and 1.13A at 0 degrees equals
ZERO volts and amps. So what we see is the darkness of destructive interference. However, we know that the energy in each of those two waves was 64 joules/sec each so the total energy involved in the destructive interference is 128 joules/sec. Where does that energy go?

We take the temperature of the impedance discontinuity and don't detect any dissipation so we can be sure that the energy has turned around and gone the only other direction possible, i.e. back toward the load. We also note that since each of those canceled waves has the voltage and

current 180 degrees out of phase, we know the energy in those two waves
was reflected energy. It stands to reason that if reflected energy is
involved in destructive interference and reverses its direction of
travel in the transmission line, it becomes re-reflected energy with the
voltage and current in phase.

Once we make it through the impedance discontinuity, everything becomes
bright and clear. Our surviving 36 watts are joined by the reflected power
from the load that has been re-reflected by the impedance discontinuity (114 watts)
and we are joined by the constructive interference resulting from the destructive
interference on the other side of the impedance discontinuity (128 watts).
So let's see how much power is in our forward wave traveling toward the load.

36W (not reflected) + 114W (re-reflected) + 128W constructive interference

equals 178W. What do you know? Everything balances perfectly and we can
proceed on to the load where 64% of our new forward wave will be reflected.

Steady-state power measurements indicate 100W forward and 0W reflected on
the 50 ohm side of the impedance discontinuity. There's 278W of forward
power and 178W of reflected on the 450 ohm ladder-line.

All dipoles are pretty much alike in performance. You might want to consider
building your own. It's something a beginner can do, and it could be even
cheaper than the dipole above. See a site like www.thewireman.com for wire,
insulators, cable, etcetera. Once you build your dipole, you may want to try
more designs!

ah, but you are required to account for all your energy. if you define the boundries of your system to be just the area around the 50-450 ohm transition you no longer have a closed system. you now have a 2 port system where you are putting energy into one port and it is leaving at the other port. since the area you are looking at has no dissipative components (assuming the line is lossless) then of course there can be no heating at that point. in the case of the resistor at the end of the 1/2 wavelength line i didn't say there was a 50 ohm resistance at the transmitter terminals, only that you could replace the whole length of line and resistor with just a resistor and you would not be able to tell the difference when measuring at the terminals of the black box. this is a standard problem out of chapter 1 of Ramo/Whinnery/VanDuzer, very simple and straight forward.

Ron,
That dipole should work as well as any other
1/2 wave dipole used in a reasonable manner. Also,
at that price, it's probably going to be about what
you could make one for if you don't happen to have
a couple of the components laying around. If the
shipping isn't included in that price, make it your
self (forget about the balun).

Bob,
Sounds like your 'crime watch' group is going well
beyond it's 'normal' duties. "Short range comms" implies
mobility, and that implies that the 'watchers' are going
looking for 'crime'. I seriously doubt if your local
police department would advocate or condone such, since
it is the police department's job to do that. 'Crime
watchers' just report suspicious activity, they don't
go looking for it.

How about trying realistically to portray the inevitable. We are half way there already.
Tom, people like you were saying the same thing in post war Czechoslovakia, "it can't happen here" until Communists threw Jan Masaryk from the window ("suicide" - jumped from the window and closed the window behind him) Then installed Gottwald for president and rest was the history - thousands of innocent people died in prisons and concentration labor camps. It took 50 years to overthrow the "righteous" government by peaceful means.
It has happened already in Australia, Canada and other countries, only to see criminality to shoot up. It starts with registration, ban of some weapons and later collection. Government by and for the people has nothing to worry about guns.
Just ask anyone from the old Soviet block what it means to live in "safe" society.

73 Safe and Merry Christmas!

Yuri

"Dave Shrader"
> A 100 horsepower automobile engine
> can deliver about 35 horsepower to the
> road! Most of that missing horsepower
> is converted into heat in the exhaust...

A "100 hp" automobile engine is not rated by the power content of the fuel flow (as you seem to imply), but by something a bit closer to the flywheel output torque and rpm. You're probably correct that the overall efficiency is somewhere around 30%, but the horsepower rating should be a 'net output' at the flywheel. A "100 hp" automobile engine should put out something close to 100 hp at the flywheel (plus lots of heat as well), and most of that 100 hp should get to the drive wheels (there is some further loss in the drivetrain, perhaps around 15-20%).

> The amount of energy, not power, in
> our COSMOS is fixed and constant. It
> was there at the instant of the BIG BANG.

Don't forget that stars convert mass into energy. I suppose you might argue that mass is simply a form of energy, but still...

The reflected part of the energy is the one which is not absorbed by radiation or dissipation at the end of the line. There is no other possibility, thus what energy can only do is ... travelling backwards. This implies (because of energy conservation at the mismatch pont) that there is a 180° out of phase current.

When there is some reactance at the mismatch point this reactance is equivalent to a modification of line length. Finally a load of R+jX impedance can be replaced by a load of R' impedance on a line slightly different in length. This case is threated easily.

73 de ON5MJ - Jacques.

Actually, if one is traveling as described, one has no time at all to think
because time is not passing.

Think of it - to an observer that rides a wave or photon in a vacuum, *no* time
elapses from when the wave leaves the generator to when it arrives at its
destination. When we look at the light from a distant star, galaxy or other
source, we say that it has taken anywhere from a few years to a few billion
years to travel from its source to us - but that's only from our perspective.
From the perspective of the light, no time at all has passed.

Not exactly. The NG server at my regular ISP is down, and I have been
trying to post using various other means. When I sent the message I
got a report back saying failure/server busy, so I tried again or used
another way. As it turns out, they were going through after all.

Dear Cecil,

Piffle, copypop, rubbish, utter nonsense!

Something may indeed happen. But because you and many others, it seems, have the phrase "reflected power" burned into your cerebral cortex nothing further can be added to this interminable idiotic discussion. Why not erase it from your vocabularies, hit the 'reset' button and evolve once more from Genesis and the big bang. "In the begining there was light . . . . . " ?

But I can't offer much hope.

Reg.

Todays amplified computer speakers seem to pickup any little bit of rf. I can take care of my own with shielding and grounding but everyone else around me has computers. Any thoughts about antenna designs that will minimize rfi? The real question to debate is which antenna will work best?

Hi Harry,

depending on type of insulation, it is around 3 - 5 %.

In my case, using electrical PVC insulated #12 wire for quad loops it was 5%.

Source record: 128524

An insulated wire has an undetectable effect on the resonant frequency of an HF antenna. It's a matter of 1 or 2 inches difference in length.

If you should insulate it to the same diameter and thickness as the stuff on your domestic hot water cylinder, and you can do an A-B test, then with precision measuring equipment you might detect a small difference.

But with thin plastic insulated wire there's no possible danger of the resonant frequency being shifted outside an amateur band as indicated on your so-called SWR meter.

Variation in height of an antenna wire above ground (which everybody forgets about anyway) has an appreciably greater effect. If you have nitpicking tendencies then all antenna wires need pruning in situ whether they are insulated or not.

A complicated calculating formula is available. But as implied above, using it is a waste of time.

It should be understood an off-resonant antenna is just as efficient as when resonant. Only a minor readjustment of the tuner may be needed.

Don't let the old-wives and magazine article writers frighten you. Ignore such malicious rumours. ;o)

QRP into a dummy load a mile away is about the only way to stay out of
amplified computer speakers. I hear guys in the Northeast receiving
WBCQ from Maine and Radio Canada on theirs.
You could probably bypass and shield everybody's speakers with some
degree of success but short of going QRT there's not much you can do at
the xmtg end.

"CW"
> A bit slow. I think.

Jacques is in the right ballpark.

Of course the average velocity for an electron depends on the current and wire gauge (in other words, current density). I did the math once for a 1 amp current in a 14-ga copper wire and it worked out to something similar to Jacques' number, but I don't recall the exact answer. But it was very slow.

For those NG lurkers that may wonder why the light comes on so quickly when the light switch is thrown - while the electrons might take several minutes...

They need to keep in mind that voltage is analogous to water pressure.

Start a distant water pump and the water at the near end (far, far away from the pump) will start to flow almost immediately (assuming that the pipe is already full of water in the same way that a wire is already full of free electrons). But the particular water that was at the pump when it started pumping (perhaps marked with dye) might not arrive at the other end for many hours.

The pressure wave (voltage) moves very quickly. The actual water flow (electrons) depends on the flow rate (current).

Reg, your bible is sure different from mine. Mine says, "In the beginning,
God created the heaven and the earth." He didn't create light until the
third verse. And as a matter of fact, the early universe was opaque and
"darkness was (indeed) upon the face of the deep".

I use a much larger Tennadyne LPDA and other LPDAs. The Tennadyne LPDAs are well designed. However, if you live where there is lots of wind or ice, you will want to reinforce the boom at the big end (slight extra cost to have done at the factory) and use plastic struts. You also want to mount a coil balun right at the boom-to-mast connection. (One piece of coax that is connected to the boom/transmission-line at the short end, run along the boom to the boom/mast bracket, and then formed into a coil that bridges the hot-to-cold transition from the boom to the mast.) The "little" Tennadyne fits to a "T" what you have told us you wish to do. Mac N8TT

Make a dipole centered on your balcony and let the ends droop down to your downstairs neighbor's balcony. Use insulated wire and, of course, get your neighbor's approval. Do NOT tell your "supe" or landlord. You can use very small wire that matches the color scheme. Be prepared to experiment. SW listening in an apartment can be tough due to interference. Touch switches, aquarium heaters, computers, and a ton of other cheap electric gee-gaws will send off signals on the exact frequency to which you wish to listen! Good luck. Please report back.

Source record: 128539

Cecil:

Cecil and Albert surfing together! I can see it now. Cecil waving
a sidearm and Albert waving a piece of chalk as they run a line at
a great beach break.

Hmmm... Yesterday I was walking along the beach boardwalk here in
Indialantic By-the-Sea, FL.

There were about 10 surfers on the waves.

Most were wearing wet suits, but a couple wore only board shorts.
Only one was female, she may have been wearing a bikini under her
wetsuit, or perhaps nothing, but I couldn't tell without my binoculors.

I am now wondering?

When you [and Einstein] are riding a wave along a transmission line,
are you also riding the current? Does the wave move in the same
direction as the current? Can you see the electrons as you ride
the wave?

Is it possible to ride an electron?
Did Einstein ever do this?
Is it more illuminating than riding the wave?
Did Einstein hate electrons as well as Quantum Mechanics?

I was born near the shorline and I swam in the waves of many
waters since my youth. I recently bought myself a longboard at
http://www.longboardhouse.com, and these days I'm trying to "catch
waves" here in Indialantic By-the-Sea. http://www.indialantic.com

As a boy I observed the waves always seem to come towards
the beach. I used to wonder if the waves in China went away
from the shorline instead of towards it.

As an adult, I have been lucky enough to travel the world. I have visited
beaches on the Atlantic coast of North and South America, the Atlantic
coast of Europe and Africa, the Pacific coast of North America, the Pacific
coast of China and Japan, and both ends of the Meditereanean. I duly
noted that the waves always seem to be moving towards the shorline.

My empirical observations have convinced me that waves never go out!
They always come in. Hence reflected waves must be ficticious or at
least suspect.

Waves... they are always hard to catch! Especially for us old guys!

So Cecil, just what is the relationship between current and wave?

Is it possible to determine the direction of a wave from a single
observation of only the voltage V at a single point/plane
on a transmission line?

Is it possible to determine the direction of a wave from
a single observation of both current I and voltage V at a single
point/plane on a transmission line?

Food for thought experiments.

A lot of theoretical thoughts. I hoped to hear from someone having
more practical experience on the subject...

> By far the greatest amount of loss occurs in the layers of soil in contact
> with and immediately surrounding a wire. That's where the transverse
> resistance of a thin layer of soil is greatest and where the greatest
> current concentration occurs.

Lets add some wild thoughts from my side. I think all agree that
current flowing through ground produces losses. When using some bare
and some insulated wires, the current, induced in the nearby ground,
will have more difficulties reaching a ground-wire, because of the
insulation. I suppose these currents will still be able to reach the
ground-wire because of capacitance effects between the wire and the
nearby ground. However that would not agree with Reg's explanation...

Arie.

> But I can't offer much hope.

i'll agree with that. 'reflected power' is probably one of the worst
phrases to hit amateur radio EVER! if everyone would only learn that
'power' is a result of current or voltage not a cause it would help. And if
they learned to think in terms of reflected currents or voltages and learn
how to keep track of them as vectors it would be much easier all around. as
many on here have seen 'power' is normally represented as a single scaler
value at a point, this hides all the complex nature of the waves that are
really doing the work. you can not work backwards from a single '100w' to
figure out the combination of forward and reflected waves that added up to
give that to you. over simplification of problems and over use of the
'steady state' assumptions in cases where they can't apply are another
common problem.

to reduce rfi by changing the antenna you have to get the antenna as far away from the problem as possible. this makes a good case for higher towers! the higher the antenna the further it is from the speakers and the less interference. the only other cure on the antenna end is to reduce the field strength by doing dumb things like adding a resistor across the terminals, making the antenna smaller and less efficient, etc.

now, there are a few non-antenna related problems that can cause this problem. pickup of rf on the shield of the feedline is one of them, if you are using coax to feed the antenna try adding some ferrite chokes to the line. this helps by keeping the rf further away from the speakers instead of letting it follow the shield back into the house. adding ferrite chokes to the computer and speaker power cords can also help, adding a filtered power strip or ups to the computer can help a bit also.

Cecil's correct.

Change the line to one that is infinitely long and open circuited. VSWR
= Infinity but the transmitter sees 50 ohms and is infinitely happy forever.

Now make the line 30 seconds long. For the first 30 seconds the
transmitter sees 50 ohms and is happy. The VSWR = Infinity and after
another 30 seconds, 60 seconds total, the transmitter absorbs the
reflected wave and increased stress occurs. My IC746 cuts back on output
power.

I don't like the term 'virtual resistance'. At the university we used
Characteristic Impedance.

Harry, my experience is in agreement with Yuri's but in disagreement with Reg's.
Building my first quad in 1965 I used loop dimensions given in the ARRL Handbook for _bare copper wire_. Ignorant of the difference at the time, I used plastic insulated wire. The quad didn't work at all - it had little or no
directivity and a terrible SWR throughout the band.

One week and a lot of tuning later I had shortened the loops approx. by one meter, ie. 5 %. Front-to-back was a respectable 25 dB and SWR was 1.

Reg may be right about the efficiency of non-resonant antennas - as long as they are _dipoles_ or Hertz-type antennas. Neglecting to consider wire insulation in _parasitic_ element antennas will most likely throw element resonances out of the band with disastrous results in both F/B and SWR.

Richard Fry wrote:
"With ZERO true reflected power, an inline wattmeter element with its typical directivity spec of 26 dB will read about 5 watts of reflected power for every 100 watts of forward power."

First, 5 watts is 5% of a 100 watt full scale. If that`s the reflected power reading into a matched dummy load, a new element may be required or you may need to re-zero the indicator meter. It probably reads 5 watts when out of service.

26 dB of directivity is not a plain numerical power ratio of 100/5, or 20.
A power ratio of 20 in plain numerical terms is a power ratio of about 13 dB.

26 dB of directivity is a plain numerical power ratio of about 400.
Therefore, an inline wattmeter with a full-scale of 100 watts could be in error due to directivity by 100/400, or by 0.25 watts, maximum.

Getting directivity of this level (reliably) is a do-it-yourself
project. Example...

Dielectric Communications makes a series of "saddle mount" RF
directional couplers designed to fit on EIA rigid coaxial transmission
line. The probe itself samples the EM fields in the line through a
hole in the coax outer conductor. The angle and penetration of the
probe determines its output voltage and directivity, and both are
adjustable by the user. The RF sample from the probe is terminated
internally in a precision, non-reactive 50 ohm load, across which the
sampled RF is available via a Type N connector. With careful effort,
the coupler can achieve 60-70dB directivity when a precision
termination is used to terminate the EIA line on which the coupler is
mounted.

Wiltron (now Anritsu) made/makes an RF bridge with ~60dB directivity,
which I have used successfully in a process to "slug" the RF output
networks of combined-parallel broadcast television transmitters so
that operational mode changes did not skew their video response.

The challenge is to be able to attach the calibrated coupler/line
assembly to the system under test without introducing reflections and
measurement error in the process.

Actually, I prefer the safety of standing on the H floor and leaning
against the E wall.

> Is it possible to ride an electron?

It's possible but you cannot know where you are AND how
fast you are going. It's not very useful.

> As a boy I observed the waves always seem to come towards
> the beach.

Your observation was inaccurate, Peter. Often, from cliffs overlooking
the Pacific Ocean, I have seen small waves heading out to sea disappear
into the big waves heading in from the sea only to re-appear on the
ocean side of the big waves undisturbed. That's what happens to reflected
waves in the presence of forward waves. Until the waves encounter a
discontinuity, they don't even know each other is there.

But you don't have to wait for waves. Toss two rocks into a pond.

> I duly
> noted that the waves always seem to be moving towards the shorline.

Go to Fitzgerald's Marine Reserve just north of Half Moon Bay, CA and
on a day with waves, you will see waves moving out to sea.

> My empirical observations have convinced me that waves never go out!

How wrong you are. You obviously didn't get the correct perspective.

> They always come in. Hence reflected waves must be ficticious or at
> least suspect.

Your experience is too limited. On any day with waves, you can see them
going out to sea along the CA coastline. There is a mismatch between
the waves and the beach and some of the wave energy is reflected back
out to sea.

> Waves... they are always hard to catch! Especially for us old guys!

Actual radio newscast circa WWII. "Today a Marine was sucked under the
Boardwalk by a big Wave."

> So Cecil, just what is the relationship between current and wave?

Don't bother with voltages and currents. Try E-H fields and everything
will be clear.

> Is it possible to determine the direction of a wave from a single
> observation of only the voltage V at a single point/plane
> on a transmission line?

Is it possible to determine the direction of an ocean wave from a
single observation of only the height of the wave? Do ocean waves
exist?

It is not just capacitive effects. It is field effects. The fields
surrounding a bare wire and an insulated wire are very much alike and
either way the fields are forming a similar pattern in the lossy ground.

Bingo, Amen!

Reg, G4FGQ writes:
>Don't let the old-wives and magazine article writers frighten you. Ignore
>such malicious rumours. ;o)

Reg,
have you ever built and compared say Quad with bare and insulated wire? I did, when calculated dimensions for 10m 3 el. quad using bare wire (EZNEC does not consider insulated wire inclusion) and built elements with insulated electrical wire, the Quad ended up right in the middle of CB band. It sure makes big difference when building resonant elements out of wire.

Looks to me that for now we can design the antenna in the software using bare wire, then adjust the elements by the shortening factor. This can be found out by constructing one element out of wire intended for use and comparing its measured resonant frequency to calculated one. Again, close approximation for PVC house wiring is about 5%.

Nice feature of modeling software is that allows us to determine the resonant frequency of the element when taken out of the antenna and then to match it while building the element (out of the antenna) for precise replication of the design.

Maybe "old-wives" that EXPERIENCED the stuff know more than those that "figured it out"?

You can call it whatever you want, I suppose, at the risk of being misunderstood by those who use conventional terminology. Reflections DO exist, and their result (melted parts) is prima-facie evidence that they can carry substantial power.

Agreed - that's why I'm staying well out of this!

This "reflected power" debate comes around here at least twice a year, and every single time, it's doomed to fizzle out in discontented disagreement. The printed version in QEX and CommQuart (SK) is even worse, because it's a series of one-way proclamations with no opportunity to reply for several months - that's just a total waste of trees.

Nobody ever wins, because nobody ever *can* win. That's because, as Dave and Reg both imply, the fault lies in the question itself.

As more and more of us come to realise that, we simply walk away.

Happy Holidays!

As a matter of fact, with the most common of ham radio configurations,
we can work backwards from a single '100w' to figure out the exact
combination of forward and reflected waves. That most common of all
ham radio configurations is a matched system where zero reflected
power flows back into the transmitter. In an ideal system, if a
match is achieved at a point, all the voltages and all the currents
are either in phase or 180 degrees out of phase. Consider:

100W XMTR---50 ohm coax---+===Some other Z0===
100W forward X watts forward
0W reflected Y watts reflected

You give me the other Z0, X, and Y and I can tell you all the voltages,
currents, and phase angles existing at the match point.

For instance, consider the one second long lossless open-circuit
transmission line. Key-down the transmitter for two seconds and then
switch from the transmitter to a matched dipole. We will certainly
be transmitting the same power generated by the transmitter just
delayed by two seconds in time.

The "wattmeter" reads a detected voltage, therefore

dB = 20*log(5/100) = 26dB

> 26 dB of directivity is a plain numerical power ratio (clip)

We have to stop here, because the directivity is specified in terms of
voltage, not power.

> of about 400.
> Therefore, an inline wattmeter with a full-scale of 100 watts could be

No. Anyway 100/400 * 100W = 25W, not 0.25W.

actually a perfectly 'matched' system is the least common ham configuration.
how often do you actually get to operate on that one frequency where you
have tuned the antenna to exactly 50 ohms(not 45 or 55), and have an exactly
50 ohm line (not 51 or 52, and completely perfect from end to end with no
connector impedance bumps)??? in commercial transmitters you can get much
closer to this ideal where you are designed for a single frequency, but for
hams a mismatch is the way of life.

if you want to analyze ideal systems please proceed, just don't try to
generalize what you think you understand to apply to real systems. Just
because in your 'ideal' system all the currents and voltages are in phase,
don't expect that to be so in a real system.

> actually a perfectly 'matched' system is the least common ham configuration.

The match doesn't have to be perfect, just close enough, i.e. reduce the reflected energy seen by the transmitter to a negligible level. It doesn't have to be a perfect system level match, just a near match at a point close to the transmitter.

> how often do you actually get to operate on that one frequency where you

Essentially every time you tune your antenna tuner for zero reflected power back into the transmitter. It's close enough to perfection for human beings.

> in commercial transmitters you can get much
> closer to this ideal where you are designed for a single frequency, but for
> hams a mismatch is the way of life.

We usually eliminate the mismatch at a match point by tuning the reflected power into the transmitter to zero. That's all that matters. I can tell you what happens at the match point. I really don't care about the rest of the system.

If no reflected power is allowed to reach the transmitter, the transmitter impedance really doesn't affect anything at the match point. And whether the load is a resistor or an antenna doesn't affect anything at the match point.

> if you want to analyze ideal systems please proceed, just don't try to

> because in your 'ideal' system all the currents and voltages are in phase,
> don't expect that to be so in a real system.

When the reflected power back to the transmitter reads zero, the values will be close enough to being in phase for amateur work. It is the standard copout to say there's no such thing as 100 volts plus or minus zero volts. Most engineers learn not to argue with the perfection of metaphysicists. If engineers had waited for your kind of perfection, man would never have walked on the moon. Engineers know their models are flawed but they will get close enough to get the job done.

We have some followers of Plato in our newsgroup. "Reality is unknowable and things are never what they appear to be." (so why bother)? Personally, I prefer Aristotle who said, "A is A". Well, he probably didn't use English but one gets the idea. He said a thing is what it is. It's not something else.

Earlier I wrote:

"With ZERO true reflected power, an inline wattmeter element with its typical directivity spec of 26dB will read about 5 watts of reflected power for every 100 watts of forward power."

On rethinking this, that rate for reflected power is incorrect. My apologies, and my appreciation to all who restrained themselves from calling me on it.

The 26dB directivity under the above conditions would produce a reflected reading on the "wattmeter" scale of 0.25W per 100W of forward power, not 5W per 100W, as pointed out by Richard Harrison.

A "first," perhaps -- someone on this NG admitted a mistake.

But note that this wattmeter does NOT read zero when there is zero true reflected power.

Richard Fry

I wrote:
"26 dB of directivity is a plain numerical ratio of about 400."

A participant protested.

You can do the math in your head!

20 dB is a power ratio of 100.

23 dB is a power ratio of 200.

26 dB is a power ratio of 400.

Further, there are no "voltage dB`s" or "power dB`s". There are only dB gains and losses. The same dB expresses separate voltage and power ratios related to the same loss or gain. Just remember that power is proportional to the square of the applied voltage and the square is equivalent to multiplying a log by 2.

Best regards, Richard Harrison, KB5WZI

Yes, engineers (and yes i are one) do know their models are 'flawed' (i prefer simplified or constrained) and they know those constraints and when they can and can't apply specific models. they also know that they can always apply the complete model that takes into account all the variables when necessary. what is annoying is that some writers have taken some of the simplified models and drawn conclusions from them that aren't necessarily accurate in the cases they try to apply them to. the 'conservation of power law' that you cite is one of them, as i pointed out there are some very specific types of networks and conditions that allows you to derive such a law, but that doesn't mean it can be applied in all cases. and specifically the case of a distributed system(feedlines and antennas are typical distributed systems) is dissallowed by the assumptions made to state the law. then there is the similar confusion about a resistor, the impedance presented by a resistor on the end of a piece of cable, and the characteristic impedance of a cable... while they all may have the same units, and in certain cases they can be mathimatically treated the same, you have to keep in mind which model you are using and under what conditions it is valid. for instance at one point in this discussion i was stating that in steady state conditions you couldn't tell the different between a resistor and a resistor on the end of a 1/2 wave length of cable... then you raised the point about video signals and their reflections, unfortunately video signals do not qualify as steady state as any engineer would know. the engineer would then use a different model that more accurately handled the conditions specified rather than trying to explain a case that the model being used wasn't meant to handle.

all i can say is, its been fun... every now and then i get into one of these discussions just to see what types of misconceptions are growing out there. you should come up to sci.physics.electromag (or is it sci.physics.relativity) where there is an almost identical discussion going on about intersecting light waves and the applicability of the Poynting vector. (the Poyting vector being similar to the power of a wave in the way that it is calculated from the E and B fields of the wave in a way similar

to power being computed from I and V, it looses some information about the wave and can't be just added together willy nilly to show what is happening.)

Hi Richard,

Returning to the Bird, and how it responds to these considerations.
The reason why standard field grade watt meters do not have better couplers, is that they have a source of greater error: their connectors.

EVERY Bird wattmeter that came across my bench for calibration suffered from connector erosion that pushed the allowable SWR specification of 1:1.05 and often worse.

There is no justification for building a more precise and directive coupler if your connectors are specified to trash the accuracy.

The Bird is the new-fangled replacement for a lamp-as-load power indicator. The meter takes less power, true, but is hardly more accurate. Richard Harrison has offered that the Bird wattmeter gives the same indication across many benches. True to the essence of its intended use, well evidenced; but again, this says nothing of accuracy.

In the parlance of Metrology there are three distinctions in reporting results: accuracy, resolution, precision. Being precise, means you can hit the same mark to within some margin of reading. Being resolved (typically expressed as having high resolution), means you can express the value of some characteristic out to 8 places such as:
1.00000001 or 0.99999999
Being accurate means knowing how much error is in the entire system.
These three terms are often mixed in discussion, each taking the meaning of another without care.

The simplest trap is found with the common DVM. The accuracy of this device may be ï¿½20% @ 1KHz and yet I am sure folks would think their reading off the speaker at 1.234V was within 1 mV of the real value. The DVM exhibits 0.1% resolution, or the ability to display 200 times more error.

Again, back to Richard Harrison's testimonial and its relation to bench activity. Much of my experience with calibration procedures and tuning instructions goes to measuring relative changes, making acceptance tests and taking few absolute readings. If any absolute power specification or declaration was made, it was typically in the form of: "Power not to exceed ... Watts."

Bench work contains very little resolution, the Bird is sufficient. At the bench, a unit is judged for its service capability, not its olympic caliber output - a peak all time best. The same goes for the class of instrumentation that monitors it.

I would venture that most commercial equipment is specified to something greater than 1dB variation across the spectrum of its production. This is reflected in a service manual adjustments going for an output of 100 to 125 W (or you note you can adjust to either). At the bench, this means one tech can tune and adjust a unit to his 5% reading of 105W; and then hand it to his buddy who adjusts it to his 5% reading of 119W and they would both be specification-on. The Bird is sufficient to this light duty too.

However, given the spec calls for an output of 100 to 125 W; then one of the techs may have opted out for a larger slug (to in fact read that greater than full scale value); a 250W slug that now casts the 125W power reading down into 50ï¿½ of full scale. Error, by specification of meter alone (5%) or 12.5W has doubled the Power determination error to 10%. That second tech, being a good one; realizes the inherent error, and the admonition not to exceed 125W and he thus derates the output to a reading of 112.5W. He can rest assured that with that reading, he is sure to fall between a true 100W and a true 125W. Through the simple change of slugs to conform to common measurements exacted by procedures, we now have the opportunity of having two techs now arrive at the same power determination at distinctly different power levels without any precise idea of what that power is (not part of their job description).

Like many other things occurring in engineering math, you can ignore
them if they are negligible or not causing a problem.

The waves are there, but until the energy meets some resistance, like the floor, they don't build in height. BTW, my surfer buddies and I distinguish between 'ground swells' and 'wind-waves'. I don't suppose there really is much difference except that wind waves are generally short-lived and run along the surface of the ocean. A nice, rideable, ground swell usually develops from storms so far out at sea that often it is difficult to find the origin. A tsunami would be considered a ground swell too. It is interesting that most boaters out at sea don't even realize when a tsunami passes beneath them.

And, you are correct about reflected waves. Where we go to find clean waves is usually behind a point break where the wave refracts around the point, and a smooth, gradual beach where reflected waves are minimized. If you have a high speed connection here's a 20 meg video of a buddy of mine on a trip we took to Baja this summer: http://www.ibscc.org/Clip148.mpg The swell for that week was from a storm that was blowing near ZL land! This point break is famous, albeit a secret. It peels for over two miles around three different points, even though my friend only rode it for 1/2 mile.

Another interesting aspect of waves in the ocean is that several waves can merge and 'sum', creating higher waves.

Hi Richard,

This is true of any meter. The hidden killer is that it is also true
for orientation. Put a Bird up high in a vertical position and take
the reading, drop it down low and lay it horizontal for another
reading. Bingo, you probably injected another 5% error with that
simple, everyday demand made on any tech in the field.

The simple fact of the matter is no one in the field makes even 20%
accurate measures, nor is concerned heavily. I would be surprised if
the Field Service manager called an all hands muster because all of
their units were running at 80%.

his Hi-Q on a car roof top. >>

Thierry-

I just came across your messages from a week or so back, and wondered how you fared.

From my point of view, your choices should primarily be based on convenience. Yes, there are differences in performance between various antennas, but we're talking only a few DBs, maybe one S-Unit at the most between the best and the worst. I'm sure you realize you won't get half-wave dipole performance from any mobile whip on 75 meters!

I'm using the Hustler with resonators on a triple-magnet mount, on the roof of my Toyota. I have a full set of resonators that I carry in the trunk, and the mast is resonant on Six Meters even with a resonator attached. The Hustler mast folds at about 18 inches when I need to put the car in the garage. With this setup and my IC-706, I've talked from Florida to California on Forty Meters, and to Africa on Ten Meters. Your band conditions may vary.

I agree that the four-magnet mount would be better assuming the same magnet size. I have had the antenna come off under certain conditions, such as the whipping action resulting from turning a corner at too high a speed. Even better would be cutting a hole and mounting the antenna on the fender. You may not like the idea of cutting holes in your car, but the magnets leave permanent rusty spots on the roof and dents result from the antenna whippinig off!

Richard-

I know I should keep my nose out of this, but I can't help myself!

That shouldn't be 100W/400 * 100W, which equals 10,000W/400. It should be 100W divided by 400 (100W - 26dB). You can do it with voltage squared divided by 50 ohms, but the results will be the same.

The use of dB for voltage or current ratios in the following is incomplete.

dB is ALWAYS a power ratio !!

So, the complete expression for the voltage case is as follows:

db = 10 log ((E2^2/R2)/(E1^2/R1)) !!!!

Now, if, and only IF, R2 = R1 then the equation is:

dB = 10 * log(E2^2/E1^2) = 20 * log (E2/E1).

Let's get real:

dB = 20*log(100/10) does not equal 10*log{{100^2/100}/{10^2/10}}.
The incorrect first answer is 20 dB the correct answer is 10 dB.

Hey Yuri, you do not need to go the old soviet block to see what happens in a "safe society". Following the authorities inability to follow the rules and guidelines already laid down for firearms licensing in the UK, we had a couple of notorious incidents involving firearms here. Some nutter in the small English town of Hungerford was allowed to amass a arsenal of firearms and decided to wreak havoc amongst the local population. Then another nutter in the small Scottish town of Dunblane takes a couple of automatics to the local school and starts blazing away.

Hungerford resulted in the banning of all semi-automatic weapons (full auto was already illegal here) and Dunblane lead to the ban on all handguns. The common thread between the two is that if the existing law had been followed correctly then neither person would have held anything more dangerous than a pea shooter. The media frenzy and the gun control lobby made sure that this was overlooked however, and rather used it as an excuse to campaign successfully for new tighter laws.

Now the only people with guns are the criminals who now have even more and even bigger guns than they had before. Gun control only hurts the legitimate law-abiding gun owner, it does nothing to deter the criminal or the dishonest. You cannot legislate against nutters who will rampage with whatever they can get their hands on, what's next - ban sticks, knives, cars, gas, lighters, matches..... you never know

From the sublime to the bloody ridiculous. Two burglars break into a farmer's house. He's been burgled loads of times before. Police are no use - he's so remote he never sees one except for his annual firearms inspection. Anyway, he shoots the two burglars with a 12 gauge killing one. Unreasonable force apparently do he's been sent down - for manslaughter I think. Anyway, the other burglar is suing him for "loss of earnings" and because the courts view him to have used unreasonable force, he will win. Absolute madness. It's no wonder burglary has been on the up and up since the war in this country - I bet they would think twice if there was a possibility they'd be

shot!

Surely the definite answer to whether or not a reflection can be ignored comes by asking the question "Is it causing a problem in this application?". Engineering is about solving problems. Leave the solving of non-problems to philosophers and politicians.

Many times I've been to a small bay surrounded by cliffs, on the California coast between Half Moon Bay and Santa Cruz, which when there is a storm off-shore will develop standing waves which don't seem to move anywhere. How does that happen?

>Is it possible to determine the direction of a wave from
>a single observation of both current I and voltage V at a single
>point/plane on a transmission line?

Of course, if you also know the characteristic impedance of the transmission line.

The V and I of a wave passing that point on the transmission line will be related such that V/I will be equal to the (normally purely resistive) characteristic impedance of the transmission line. If the value of V/I you compute from your measured V and I is real and equal in magnitude to the characteristic impedance of the line, then the sign (i.e. the phase, either 0 degrees or 180 degrees) tells you the direction the wave is going.

If V/I has an imaginary component (i.e. their relative phase is not 0 degrees or 180 degrees), or if its magnitude is not equal to the characteristic impedance, then the only way the measurement can be consistent with waves moving at the characterstic impedance of the transmission line is if what you are measuring is the superposition of two waves, one (say V+ and I+) travelling in one direction on the line and the other (say V- and I-) travelling in the other, where V+/I+ and V-/I- are each individually equal to the characteristic impedance of the transmission line. Relating this to the measured V and I, on a 50 ohm transmission line for example, gives

V = V+ + V-
I = I+ + I-
V+/I+ = 50 (or 50 @ 0 degrees)
V-/I- = -50 (or 50 @ 180 degrees)

That is 4 independent equations, which can be solved for the 4 unknowns, so the single measurement of V and I plus the line's characteristic impedance gives you the amplitude and relative phase of the waves going in each direction.

I personally think all the confusion here comes not from waves themselves, but with the notion that there is a "reflection coefficient" at each impedance discontinuity having a magnitude which depends solely on the transmission line characteristic impedances on each side of the discontinuity. I think a better (i.e. closer to reality) way to look at it is that the reflection coefficient for a wave approaching a transmission line impedance discontinuity is a function of both the transmission line impedances and the amplitude and phase of the wave approaching the discontinuity from the other direction, with the reflection coefficient computed based on transmission line impedances alone being a special case which only applies when no wave is approaching the discontinuity from the other direction. For the current problem we would then just be able to say that the reflection coefficient at steady state for a wave approaching the junction of the 50 ohm and 450 ohm transmission lines from the 50 ohm side is 0, and from the 450 ohm side is 1 (or -1?), and we would need to introduce neither magic addition for scalar power nor mystical "destructive interference" which makes power disappear at one spot and pop out at another. Both of the latter only exist to try to make the result consistent with the "reflection coefficient" of 0.8 which is computed from the transmission line impedances alone, and the magic devices wouldn't be required if we just concluded that the computation which produced 0.8 didn't apply at a junction with waves approaching from both directions.

Nobody bothered to mention what was the conductor diameter, the diameter over the insulation, the type of insulation, permittivity, and the diameter of the bare wire which replaced it. All essential factors in such experiments.

Or how careful lengths were measured. And were there other factors which changed when the type of wire was changed. A different SWR meter? A change in the length or impedance of feedline? It is fatal to determine antenna resonant frequencies using SWR meters. Especially when only small shifts are expected.

Hello Mike, You can use a bazooker, that is a length of copper tube 1/4 wave long slid over the feeder.
It is bonded to the feeder at the remote(lower) end, and insulated at the termination end where it connects to the antenna.
You did not say what frequency, if tube is too long use braid removed from coax, it can be slid over and cut to length in situ.

Dennis,

Regarding "standing waves", as a surfer/windsurfer I can tell you there are three things that could be happening: 1) a stiff offshore wind, as often happens at various points along California, will hold up the wave face slightly 2) there's a rip current travelling opposite the direction the wave (usually more common on the East Coast due to weird sand bars and channels) 3) A fast moving swell hits resistance along the bottom the actual speed slows down. The energy of a wave in water is circular. When the floor of the ocean interrupts the circular movement, the wave pitches and consequently breaks over itself.

Here's a shot my girlfriend took of me at a point break in San Simeon (yes, I trespassed on Hearst property this summer) http://www.ibscc.org/cali.htm This spot is a favorite for the reasons above. The wave 'walls' up and holds position long enough for us to play on its face without fear of getting overtaken.

If you're familiar with The Columbia River in Oregon in summer, you'll know exactly what I mean about the current flowing opposite the waves... There the river flows approx 10 miles/hour while the waves might travel 15-20 mph against it. From the shore it looks like the waves move very slowly up river

Well, if one is a criminal anyway, might as well break the law with a full automatic rifle rather than a six-shooter revolver. I've been told there are no more Bobbies on bicycles patrolling the streets because they are too afraid of the criminals. If an armed Bobbie is afraid of the criminals, what about an unarmed citizen? It appears that gun prohibition is working in England just about as well as alcohol prohibition worked here in the USA.

...I read here...

"Can V and I get out of phase on a line and if so what is cause and consequence and how do you know?"
============

If one is talking about the traveling V and and I waves as opposed to the standing V and I, there will indeed be a non unity power factor (phase angle > 0) if the charateristic impedance of the line has an imaginary conponent, i.e., is not real.

For RF lines the Zo is so close to being real that V and I will indeed be in phase and the p.f. is .999999999...

Well a 3:1 VSWR produces a decrease in received signal of about -1.25 dB. This is non noticeable in all but weak signal work. So for HF a 3:1 VSWR is a non issue relative to two way path loss [ability to communicate]. So I don't have to do anything regarding path loss.

Now a 3:1 VSWR is excessive for my IC-746 and it will initiate a reduction in output power to protect the 746 from damage. So, if I want full output from the 746 I have to do something to reduce the feedpoint VSWR.

Also, a 3:1 VSWR on 80 CW with my tuner and balanced line to a center fed doublet will cause my tuner to arc over at power levels above 800 watts output. That's not very kind to my 3-500's. So, I have to do something to protect my 3-500's.

Based on my history, a 25% reflected power is a non issue for communications purposes; but it causes a systems problem regarding wear and tear on my station equipment.

I thank Mr. McCoy for the design of the Ultimate Transmatch made by Murch Electronics that I use to achieve a conjugate match for my 746 and/or amplifier and center fed doublet. It is the 'SOMETHING" I use to solve any VSWR 'problems' [sorry, reflected power problems] I may have.

I do not have a 'reflected power' problem on any frequency between 13.5 and 33 MHz. My antenna has almost 6 dBd gain across all frequencies in that range and exhibits a maximum VSWR of 1.6:1 across all frequencies in that range. The nominal VSWR is 1.3:1 to 1.4:1.

Deacon Dave, W1MCE [for almost 50 years]

I found the only way to cure the problem is to move into a neighborhood that has no computers...hi.

The speakers sold are trash. For some reason I have some that DO NOT GET BLASTED. And I run them right in the shack on my puter. The name on them is JUSTer Multimedia...AC691N is the model number. Got them years ago on a Prokek computer.

Two years later we bought another Protek for the wife. Her speakers get blasted all to pieces. She just turns them off.

No problem until the neighbor across the way got a puter...you guessed it...blasted the speakers.. I tried it all...bypass, beads, moving wires. etc. I finally switched speakers with him and for 2 years it was no sweat. He then decided to sell his house. So I bought it to keep another computer out of my RF field....grin. I did buy the house tho.

I recall Einstein thinking about riding on trains a lot, but I
don't recall where he thinks about riding on light. In any case,
if you managed to do this you certainly wouldn't be carrying a
lot of mass along with you to think with, since the general theory
says that to do that with mass you'd need to apply infinite
energy, and infinite energy isn't available even in theory.

> Let's ride the forward wave from the transmitter to the load

>As we get closer to the impedance discontinuity, we realize that we
>have already achieved steady-state conditions and a large destructive
>interference process is in progress which tells us there is an impedance
>match happening at the impedance discontinuity.

I don't see how you could know any of this from your point of view on
the wave.

First, you are already approaching the impedance discontinuity at the
speed of light so I don't know how you could "see" it ahead. At the
speed of light there is no way to get information about what is ahead
of you any sooner than you, yourself, will get there. All you'll be
able to observe from the 50 ohm side of the impedance discontinuity
is the 50 ohm wave you are riding on and, perhaps, whatever energy
is headed in the other direction on the transmission line at the point
you are at.

For the other direction, however, you suggest you can see "a destructive interference process" going on over there. I'd like to know exactly what is it this looks like? How did you recognize it? As far as I can tell this process involves no net energy, and because of this it cannot be observed. That is, "a destructive interference process" is indistinguishable from nothing at all, so I think it is a lot simpler to just refer to it as "nothing at all".

So what you are really seeing from your wave on the 50 ohm side of the discontinuity is the 50 ohm wave you are riding in the forward direction, and nothing at all going in the other direction. You ride along, blissfully ignorant of what is to come until, bang, you zip past the discontinuity and suddenly find yourself riding a 450 ohm wave, with another 450 ohm wave going past you in the other direction, but with all the energy your wave had on the other side of the discontinuity making it to this side. You couldn't tell anything before you got there, though after the fact you can observe that something happened to the impedance, but that 100% of the energy in your wave made it across the impedance boundary and 0% got reflected.

Note, however, that the 64% number appears no where in your observations. There is just no 64% number involved anywhere you can see, whatever happened here had nothing to do with 64% of anything at all. Now at this point you might be tempted to complain that, since you observed the transmission impedance on the 50 ohm side and can see it now on the 450 ohm side, that 64% "should have been" involved somewhere even if you couldn't see it. I don't think this is relavent to much either, however, since you wouldn't be aware of even the numbers from which to compute 64% if you'd picked another wave to ride.

In particular, if the wave you were riding were instead the reverse-travelling wave on the 450 ohm line, you'd see even less. On the way towards the 50 ohm junction you'd be able to see the 450 ohm wave you were riding, and a bigger wave going in the other direction, until you get to the impedance discontinuity where, bang, 100% of the energy in your wave turns around and heads back where it came from and 0% makes it past the discontinuity. So, on this wave, not only do we find that the 64% can't be observed anywhere but that, since none of our energy made it past the discontinuity, we can't possibly know what was on the other side so we can't even compute that 64% "should have been" involved. All we know is that 100% of our energy was reflected and 0% made it past.

Now I'll just point out that your unobservable, mythical "destructive interference process" is just as dubious as Steve's magical vector addition of scalar powers, and that both of these are being introduced for precisely one purpose: to somehow make the results consistent with the 64% number, or the +/- 0.8 reflection coefficients, you compute for the impedance discontinuity based on the transmission line characteristic impedances alone. If you didn't attempt to make use of the +/- 0.8 number (which can't be observed anywhere

in the end result, the end result has a reflection coefficient of
0 in one direction and -1 in the other) in the first place neither
of you would need to introduce these odd devices, that do nothing
to help actually solve the problem, to show that 0.8 is there even
though you can't see it.

So to eliminate the need for either of these extra devices used
to work 64% into there (and in doing so to apply Occam's Razor), I
think the simplest view is that the reflection coefficient for
one side of an impedance discontinuity is always a function of the
two respective characteristic transmission line impedances *and* the
relative amplitude and phase of any wave approaching the discontinuity
from the other side. That is, you can't compute a reflection coefficient
unless you know all of these things. This means that the reflection
coefficient you compute based solely on the impedances is actually
a special case that only applies when you know the wave approaching
the discontinuity from the other side has zero amplitude, and
applies not at all in any other case, like the 50/450 ohm discontinuity
in your case where you have waves approaching in both directions.

Now that we know that the reflection coefficient is not +/- 0.8
for the impedance discontinuity in your problem, we won't compute
0.8 but instead can just compute what the reflection coefficients
really are for each direction. In this case `rho' is 0 in the
forward direction on the 50 ohm line and is -1 in the reverse direction
on the 450 ohm line, and the lack of any detectable waves on the
reverse direction on the 50 ohm line is due to the fact that, with
no reflection of the 50 ohm forward wave and no transmission of
the 450 ohm reverse wave, no waves ever make it to the reverse
direction on the 50 ohm transmission line in the first place. With
no waves over there in the first place you then don't need to make up
wierd mechanisms or odd math to explain where the waves went, and life
is simple.

5358. Insulated Antenna Wires and Californian Grapes.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-24 02:56:45 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <au8idc$ir6$1@sparta.btinternet.com>
Source record: 128445

The efffect of an insulated covering of an antenna wire is to increase its capacitance per unit length. It has no effect on inductance per unit length. So the result is a decrease in propagation velocity along the wire relative to that of light. As with any other transmission line, as Terman probably agrees, the velocity decreases according to the square root of the increase in capacitance. There are no other significant effects.

The problem is to determine the increase in capacitance over that of a bare wire due to an insulating marerial of given thickness of given permittivity. Clearly the capacitance of the bare wire to its surroundings must be taken into account and this can be estimated from a sensible model. Models will vary. As I have been unable to re-discover my ancient notes I have spent the last three hours going back to square one fortified by 3/4's of a bottle of Californian medium white whine from Ernest & Gallo's celebrated cellars, dated 2001.

Let's take as an example the North American most popular antenna - a 40m band 1/2-wave dipole at a height of 1/4-wavelength above ground. This may be considered as a worst-case model.

After much ball-point and paper tt turns out that the ratio of antenna capacitance, with and without wire insulation, is given by -

K*Ln(4*H/d) divided by -

K*Ln(4*H/D) + Ln(D/d),

where H = antenna height above ground,

d = wire diameter,

D = diameter over wire insulation,

K = permittivity of insulating material,

Logs to base e.

For PVC, permittivity is in the same ballpark as 4.

Let H = 33 feet, Wire diameter = 18swg, Diameter over wire insulation = twice wire diameter, Insulation = PVC.

RESULT: To maintain the same dipole resonant frequency after insulating the wire, cut off 10 inches from the ends. which is less than the value of the "end effect" which people take notice of only because of the importance attached to it in the handbooks.

If an insulated wire is replaced, as would normally be done, by a bare wire of greater (copper) diameter the difference in resonant lengths would be

even smaller.

With enamel insulated wire (for weather protection - it really works!) the
resonant length is completely unaffected.

> 'Doc

Nothing could be further from the truth! They do have "window watcher" members in this group but in fact, most law enforcement sanctioned crime watch groups recommend that their patrols use two-way radios. Whether or not cell phone service is available (its not reliable in this rural area), it is always useful to have comms for the patrols. This group is mobile and is patrolling neighborhoods to "OBSERVE AND REPORT" suspicious and criminal activity to the police. The patrols even have amber rotating beacon light on the roof of the vehicle to identify themselves as the watch patrol. (They also patrol on foot an bike using HTs)

You have a very narrow view of what crime watch groups do. They DO go out looking for it in neighborhoods. In fact, its been proven that having patrols looking for activity actually helps to deter criminal activity. They just don't engage suspects or pretend to have police powers. Believe me, law enforcement appreciates the extra sets of eyes - especially if they are mobile!

BTW, the local law enforcement officer that is the liaison to the group wants to install the crime watch freq into the police vehicles' radios so they can communicate directly with the patrol on scene. So I guess you could call that a condoned activity, eh?

Think this group is unique?

It would be easier to just get a separate 2 meter antenna. If the repeaters are within 20 or 30 miles, one effective option is to get a mobile whip in a magnetic mount, and stick the mount to any indoor metal surface. I've used one on a metal serving platter. Works great.

The mfj antennna, by the way, is patterned after the B&W AP-10a, which I've used in an apartment for hf contacts -- stick it in the window, unroll the counterpoise wire, and it actually gets out fairly decently on the higher hf bands.

That's nothing, look at this insanity right here in NJ (liberals in action):

TRENTON, N.J. (Dec. 23) - New Jersey on Monday became the first state to enact ''smart gun'' legislation that would eventually require new handguns to contain technology that allows only their owners to fire them.

However, the bill signed into law by Gov. James E. McGreevey will not go into effect immediately because the technology is still under development. It could be years and cost millions before the technology becomes a reality.

''This is common-sense legislation. There are safety regulations on cars, on toys. It's clearly time we have safety regulations on handguns,'' McGreevey said.

Under the law, smart-gun technology will be required in all new handguns sold three years after the state attorney general determines a smart gun prototype is safe and commercially available. Weapons used by law enforcement officers would be exempt until a separate decision on whether the requirement should apply to them.

The New Jersey Institute of Technology is developing a smart gun prototype that would use sensors on the pistol grip to identify a user.

The owner would have his or her grip programmed at a gun shop or police range by practice-firing the weapon. A microchip in the weapon would remember the grip and determine in an instant whether the authorized user was holding the weapon. If not, the gun would not fire.

NJIT researchers said a viable prototype can be developed in about two years but would require $4 million to $5 million in additional funding, which has yet to be approved.

''What we have is a demonstration concept,'' said Donald Sebastian of NJIT. ''It is not yet a proven technology.''

Gun manufacturer Smith & Wesson was awarded a $1.7 million federal grant last year to develop the technology and has spent $5 million on development since 1993.

Opponents argue that it makes little sense to legislate a requirement about a technology that does not yet exist. They have also raised questions about its reliability.

''No technology is foolproof,'' said Nancy Ross, spokeswoman for the Association of New Jersey Rifle and Pistol Clubs. ''Anyone who has a computer knows how many times it crashes.''

Similar bills have been introduced in Congress and in other states, including New York, Ohio and Tennessee.

Hey Reg, you sound like some Fractal professor, or W8JI who when wrong, tries to dance out of it.
Try to build at least 10m dipole, first using calculated length of bare #12 wire, and then the same length using say PVC insulated #12 house wire. Choice of instruments is yours. You will find that "insulated" antenna will be about 4 - 5 % lower in resonant frequency.
I use also SWR meters to determine resonant frequency and am stil alive to tell about it, ain't that fatal :-)
You can use RF bridge, MFJ analyzer, SWR bridge, you name it, results will be the same.

That's just it. We are expecting to see some brightness from the reflections from the impedance discontinuity. But all we see is darkness. We don't see the brightness until we pass the impedance discontinuity.

So you would rather imagine a metaphysical virtual reflection coefficient that doesn't exist in reality??? That's really an improvement over the actual physical reflection coefficient????? Everything can be explained without a belief in the supernatural. Everything can be explained with the actual physical reflection coefficient.

Too bad that virtual reflection coefficient is an effect rather than a cause and cannot be the cause of anything. You too, have been seduced by the steady-state model.

> That is, you can't compute a reflection coefficient
> unless you know all of these things. This means that the reflection
> coefficient you compute based solely on the impedances is actually
> a special case that only applies when you know the wave approaching
> the discontinuity from the other side has zero amplitude, and
> applies not at all in any other case, like the 50/450 ohm discontinuity
> in your case where you have waves approaching in both directions.

The actual physical reflection coefficient is the only one capable of
causing anything. Everything else is an effect.

> Now that we know that the reflection coefficient is not +/- 0.8
> for the impedance discontinuity in your problem, we won't compute
> 0.8 but instead can just compute what the reflection coefficients
> really are for each direction.

But your virtual reflection coefficients are not really there. They are
only virtual and cannot cause anything. You have been seduced.

<< My Bird wattmeter reads so close to zero reflected power when connected to a Bird dummy load that I can`t see any difference. Maybe my slugs are extra good. >>

Richard-

I believe the 26 dB that was mentioned earlier, was a "worst case" value.

Another thing to consider is the detector diode's non-linearity for small signals. Below a certain power level, the value of the voltage sample will fall off more rapidly than the actual power present.

Your Bird meter might indicate some reflected power if a lower-power slug were used. However, you would have a hard time determining if it was due to the slug's sensitivity to opposite-direction power or to actual reflected power.

Yes.

The point is that Richard Fry is creating a diversion from his mistake with decibels by making a false impression with an assertion that: "But note that this wattmeter does NOT read zero when there is zero true reflected power."

Fact is that balance is reasonably good in the Bird wattmeter. 26 dB is a power ratio of 400 to 1.

Certainly nothing is perfect, but 1/4% reverse response is not bad. Even this "worst case" response would be hard to read on a meter.

Best regards, Richard Harrison, KB5WZI

Radio Shack sells a BNC-connector window mount (not magnetic). It is intended to hold a rubber duckie antenna (or any small BNC mount antenna). It is a bent bit of metal that wraps around the top of the window and has a cable about three feet long. The antenna (not included) plugs into the BNC connector.

They would not be suitable for cars with power windows and tight fitting glass and weather stripping (potential for cracked glass). They also wouldn't work if the side window glass was deeply recessed as compared to the roof.

They were on clearance sale here in Canada and seem to be sold out. I was in FL recently and they seemed to be a current item. I don't recall the price, but probably around US$10.

The only diversion here is toward an understanding that more accurate means of measuring EM fields in transmission lines than provided by "in-line directional wattmeters" DOES exist.

Whether or not that level of accuracy is appropriate for radio amateurs is another matter.

That's how the Discovery Channel said he envisioned what might happen
to things traveling at the speed of light when they encounter things
at rest. A lot of us have surfed on water waves so envisioning surfing
on an electromagnetic wave can be an interesting and enlightening thought
experiment.

> More probably, he was just pulling your leg, Cecil.

I know he was pulling our legs when he said, "God doesn't roll dice."
Was it Schrï¿½dinger who said, "Not only does God roll dice, but
He rolls them in the dark."?

L. B. Cebic W4RLN has a very interesting paper on his site re insulated wires when modeled with NEC-4. (which I don't have). However he does furnish data and curves to qualify his exercise. But I will say from practical experience in the northern latitudes, when a snow storm comes up like last evening, precipitation static would have wiped out my sked on 160 had I not had insulated wire. (the military and commercial people found this out long ago) Of course my DSP NR helped as well. But when it comes to resonant wires, in my 53 years of putting them up, even with modeling I have yet to get one right the first time. Wire antennas are cut and try. Keith, VE3JKC.

That will not explain why the light turns on quickly. It takes voltage AND current (ie, power) to light a light bulb or do any other "work."

If the bulb had to wait several minutes for the current to arrive, it would be dark until then.

Hi Cecil,

I thought your sources were particularly slim. You misquoted Einstein
twice in the space of two quotes (or attributions, rather).

Einstein did not come up with the idea you propose (and which you show
ill-understanding of - even at the Discovery Channel grade).

Jim was right about there being no time at the speed of light, this
was an observation Einstein repeated from two other researchers who
already described this effect years before. For a closer reading, I
would suggest once again, you should avoid Physics coverage from
derivative works (especially bench level engineering or technical
books); you rarely get these topics right when you lean on these weak
sources.

There were two men who pre-date Einstein in this regard of travel at
the speed of light: Poincarï¿½ persuaded Einstein to contemplate
Lorentz's work on what are called Lorentz Transformations. What you
are quoting is not Einstein, it is Lorentz and his work. Einstein did
not do the work, he merely reported it. You did neither the work, nor
did you follow exactly what Einstein said either. The work,
Lorentzian transforms, are quite simple employing common high school
Algebra I concepts.

Lorentz showed some interesting facts about the "physical world" at
the speed of light (there being no such thing, is equivalent to this
so-called thought experiment). Riding such a crest would present you
with the forward and backward dimensions collapsed to zero. You
cannot see ahead, you cannot see behind. At the speed of light, there
is no distance between the source and the load. Riding such a crest

would present you with a flat dimension (in quadrature to apparent motion) that is infinite in expanse. Riding such a crest would present you with the collapse of time to zero as well, At the speed of light, there is no time interval, everything is simultaneous. At the speed of light, any physical entity would have had to had the energy of an infinite cosmos required to boost it to that speed.

There's that copout word, "exactly", again. I dare say you are not
quoting anyone "exactly" either. I'm pretty sure that Lorentz didn't
write in English. And I think I learned about Lorentz's transformations
about 50 years ago. I think they explain the universal red shift better
than does any Doppler Effect.

> Lorentz showed some interesting facts about the "physical world" at
> the speed of light (there being no such thing, is equivalent to this

Not if I do it in my mind. You see, it is a *thought* experiment.
Einstein didn't have to travel at the speed of light to envision himself
traveling at the speed of light. Neither do you or I.

> At
> the speed of light, any physical entity would have had to had the
> energy of an infinite cosmos required to boost it to that speed.

You haven't told me anything I didn't already know. Yet you have not
stopped me from riding those waves in my mind. Good luck on that quest.

Maybe you should try it sometime, Richard. It will literally open your
eyes and mind. It might help if you use a photon surfboard to stand on.

Source record: 128474

I want to put up one light inverted-V dipole-type antenna when camping
that will handle 40M and 80M QRP.

Options so far considered include traps, loading coils and a fan
arrangement.

Since I need to guy the pole anyway, How about running a half-wave 80M
perpendicular a 40M half-wave dipole, with both connected to the same
feedpoint, fed with twinlead?

I have tried to model this on EZNEC, but could not figure out how to
get the split source feature to work with a 4-wire junction.

Hi Cecil,

Well.... It stands to reason that I cannot apply the word "correctly"
to your quotes either if you get your knickers so easily bunched up.

Tell us about copouts and editors, Cecil. Don't let it get you down,
Buckaroo; it all look so much better in print. ;-)

What practical alternative exists for radio amateurs?

The amateur is often changing bands and frequencies. The old amateur
method to determine power was to measure power input to the final
amplifier and estimate the power radiated.

Use an r-f bridge to find the resistance of the antenna load at a
particular point in the feed system. Then measure the r-f amps at that
point. The power can be calculated from I squared R. The FCC mandates
this method for AM broadcasters. The power can be continuously monitored
as a function of the r-f amps this way.

An amateur would have to find a feedpoint resistance for each
transmitted frequency.

What more accurate means of measuring E-M fields in an amateur`s
transmission line is practical?

Best regards, Richard Harrison, KB5WZI

You do not need any kind of antenna tuner. You might need an adaptor on the T/R relay. Can't remember off the top of my head, but I think the Heathkit 220 open circuit relay control voltage is a lot more than 12V. Use almost any coax you want; any reasonable length of RG58 is OK.

If you are going to feed it with twinlead, why not put up an 80m
dipole and feed it with 1/2WL of twinlead on 80m and 3/4WL of twinlead
on 40m? - no tuner required.

==========

All radio amateurs and 99% of professionals, when it comes to measurements severely suffer from delusions of accuracy.

This results from gross neglect of the study of elementary statistics in their very early education.

Any measurement which appears to confirm an old wives' tale is recorded as a success, even published in learned articles, magazines and newsgroups. All measurements to the contrary are discarded as errors and conveniently forgotten about.

Not that it matters very much - radio is by far the most inexact of all the sciences - not that it deserves that name.

Fortunately for the fraternity, any bloody thing will work! And it's great fun, eh?

This water analogy may be getting a bit strained; but with water, this is no big mystery.

Assuming a valve is open at the far end, water will start to flow out as soon as the pressure wave gets down there. (Pipeline is assumed to be full when you start, natch.) You don't have to wait several minutes for that flow to occur--unless we're talking about the California Aquaduct or something. Of course, the specific water that flows immediately from the far end is the water that's already down there. "New" water from the sending end will take much longer to arrive.

You are free to substitute electrons for water in all this, at your own risk.

The problem is not the speed of light. The problem is the depth (or lack thereof) of human thought. Are you familiar with modeling large ships floating on water by using smaller scale ships floating on glycerin or oil?

What I am doing in my thought experiment is slowing things down to human speed. It's somewhat like flying above a tsunami wave in a jet airplane, matching its speed. We are looking ahead and see the shoreline of an island directly in the path of the tsunami. The results are predictable.

In my thought experiment, we have a simulated EM wave traveling toward an impedance discontinuity. The wave model predicts what is going to happen. If we meet any waves traveling the other direction, they will pass us unchanged. In fact, the only thing that can change a wave in a lossless transmission line is a real impedance discontinuity accompanied by reflections and merging of waves traveling in the same direction. A virtual reflection coefficient is the *result* of a virtual impedance. A virtual impedance is the *result* of a particular V/I ratio. The particular V/I ratio is the *result* of reflections and interference of component waves around a *real* impedance discontinuity. The reflections and interference are the *result* of a real impedance discontinuity plus coherent source wave energy flowing into the impedance discontinuity often from opposite directions.

A virtual reflection coefficient is the final end result of the process and NOT the cause of anything except arguments on r.r.a.a from people who have been seduced by the steady-state model. :-)

Hi Cecil,

Naive too I see. You've offered exclusive rights to a vanity rag for
the sake of -maybe- seeing your name in print? Tacit admission on
your part that there is no one else interested. Months from now? Too
coy by half. I suppose this takes the pressure off of the IEEE
editors on how to approach your ground-breaking work. ;-)
Or did you save some of your proof for yet another article?

Not too odd, that last notion. You've admittedly been giving us half
the story for months now. You must be aiming to do a series - good
luck.

You shouldn't need to use a tuner between the rig and amp if the amp input
is tuned properly. But you should probably use an external keying relay to
protect the rig from the amps' keying voltage/current.

> also what type of coax and length between the two ? Thanks, Sam

Type - 50 ohm
Length - Long enough to reach from the rig to the amp.

They don't have exclusive rights unless they decide to print it.
If they don't print it, I will go elsewhere.

> Tacit admission on your part that there is no one else interested.

Worldradio has published everything I have submitted to them. But
this might be a little too technical for their publication as it
relies on the EM wave model, the superposition principle, and the
conservation of energy principle.

> Months from now? Too
> coy by half. I suppose this takes the pressure off of the IEEE

It is not ground-breaking work, Richard. I was taught this stuff
at Texas A&M almost half a century ago by a host of knowledgeable
EE professors. It is apparently knowledge that has been replaced by
seductive shortcuts and lost during the last 50 years. I am just
trying to re-introduce my fellow hams to those ancient concepts and
principles. I'm sure the IEEE wouldn't be interested in stuff
I learned at Texas A&M in the 1950's.

Cecil, I'm sorry to say your question illustrates my earlier point about the general lack of schooling on the subject of statistics.

Multiple errors have a nasty habit of statistically accumulating.

Apparently you are unaware of all the other many sources of error in a measuring set-up.

Do you recall your so-called 450-ohm ladder line which (you think!) actually has an impedance of 390 ohms. That makes a mess of your analysis of switched variable-length ladder-line tuners.

What you don't know is the Zo of lines used by all the other people who have attempted (unsuccessfully?) to reproduce your findings.

All you know, found purely by chance, is that YOUR set-up works.

As a side issue, the Zo of the line used in the G5RV has never been specified not even by the great man himself. All he ever said was that it should be 1/2-wavelength long somewhere in the 20m band. It's not surprising the performance of the G5RV has been a matter of dispute amongst waffling old wives and Ph.D's for many years.

Yes, I know we're only amateurs. ;o) ;o)

The Assessment and Summation of Measurement Errors is a vital subject at the very root of all Engineering disciplines and Sciences.

Or (forgive an old English phrase) am I teaching my grandmother to suck eggs?

Cec, let us all have a very pleasant Xmas and, if we can get rid of the two B's, a peaceful 2003.

Yours, Reg.

Why? It works essentially the same with 300 ohm ladder-line as with
450 ohm ladder-line as with 600 ohm open-wire feedline.

3/4 wave will 'invert' the high impedance to something lower...right
down to 1:1 if you trim the feedline accurately.

Nope, it doesn't. With a 130ft dipole on 7.2MHz it shows SWR = 11.2:1
on the 450 ohm ladder-line and 1.25:1 on the coax. On 3.8MHz, it shows
6.6:1 on the 450 ohm ladder-line and 1.4:1 on the coax. Like I said,
no tuner needed. I know. I run that 130ft dipole on 75m and 40m with
no antenna tuner. My transmitter is perfectly happy.

> My SWR meter doesn't go that high. Also, I am concerned that I will
> fry my radio.

Do you know how to use the transmission line option in EZNEC?
If so, adjust the feedline length on 80m for a match. Then adjust
the feedline length on 40m for a match. On my dipole, the lengths
are 110ft and 92ft.

If you plan on working 80 and 40 only, I would feed with coax. Will be
less loss than if you use a tuner and twinlead. You could use Cecils
ladder line method, but you will have to switch feedline lengths to
change bands. You would not have to do this with the coax, and also
the coax can lay on the ground, and also get wet. For qrp, I'd go with
the coax. Will be less trouble, and very low loss if you use decent
coax. Even rg-58 is fairly low loss for those two bands. Rg-8 or 213
would be very low loss. I use the same exact setup for portable use on
those bands if I string up dipoles. "80/40 dipoles parallel, fed with
coax". Whatever you do, if you run QRP, I would avoid using a tuner if
at all possible.
Won't need one for coax fed dipoles, or Cecils ladder line method. I
think the coax is easier to deal with though.

5410. How much difference does a resonant antenna make?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-25 06:26:12 UTC
From: Bob Cameron <bob.cameron.remove@optusnet.com.au>
Message-ID: <52jbua.hrh.ln@p400bob.lse.com.au>
Source record: 128499

Hi All

Silly question time.

For quite some time I have believed that for an antenna to work well it needs to be resonant at the operating freq. Ie no reactance at the feedpoint.

My question is how important is that really? If (for example) I start off with a quarter wave groundplane (feedpoint 37 ohms resistive) and test its "perfomance" (VSWR approx 1.5:1), then alter its length so that the conjugate impedence is 50r and test again, what "difference" is noted?

A measurement in dB would be useful?

I guess I should ask whether it changes from antenna type to antenna type? Eg quad vs dipole vs yagi etc etc.

Cheers

Bob (VK2YQA)

No, it doesn't matter too much on the length. What matters is how
efficiently you can feed power to it. The difference on paper of a
full 1/2 wave dipole, and a half sized dipole are small. Maybe .3 db.
But in the real world, the smaller antenna will generally be down a
good bit due to losses in feeding the low impedance-high reactance
load. For most people using tuners and ladder line in such a case,
most of the loss is in the tuner coil.

>

Depends where the increase in impedance came from. You could add
ground losses, and increase the feedpoint impedance and lose
performance. Or you could simply fold the radials down at a 45 degree
angle and see little if any difference if the ground losses stayed the
same. Maybe even a small increase due to acting more like a 1/2 wave
vertical.

> I guess I should ask whether it changes from antenna type to antenna type?
> Eg quad vs dipole vs yagi etc etc.

Not really. It's not the size, it's the efficiency or lack of it in
feeding. But saying that, I'd still prefer a full sized antenna over a
small one , all other things being equal. Even efficiency in itself
can be deceptive. Many times it's the least efficient antenna that
wins to a certain path at a certain time due to a optimum takeoff
angle for that path/time. I've seen my mobile antenna beat a 35 ft
high full size dipole on 40m at night to a path of about 900 miles.
And it did it over and over again. Wasn't a fluke. The mobile was just
putting it's power at just the right lower angles, where the dipole
wasted much power at higher angles that were not being used.

Bob, your base assumption regarding antenna resonance is in error.

Basically any conductor of reasonable length will be an effective antenna. The issue is not resonance but coupling the RF to the antenna.

I use an approximate 200 for center fed doublet with 600 ohm tuned feeders for 80/75, 40 and 30 meters.

In your example the 1/4 wave ground plane would give a low angle of radiation. Increasing it's length will change the angle of radiation. It would go above the horizon. You may need a tuning network at the antenna or at your radio to couple energy into the antenna.

Put 100 watts into a 1/4 WL and get low angle radiation. Put 100 watts into a 3/8 WL and higher angle of radiation. Put 100 watts into a 1/2 WL vertical and get low angle radiation. As the length gets larger than 1/2 WL, resonant or non resonant, the antenna pattern develops lobes, gain over a dipole, at some angle.

But it does not have to be resonant.

The appeal of this method vs. the fan+coax is that twinlead is lighter
than coax and only one dipole is needed.

Your feedline lengths for twinlead (300 ohm) seem to be the same as
for ladder (450 ohm). Is this correct?

On your web page you show some of the adjustable ladder stubs being
loops. What about the main length? Does it have to run straight and
be high in the air? Or can it lie on the ground snake-like (without
crossing or loops coming close to each other)?

That's an old wives' tale, Bob. An Extended Double Zepp is not
resonant at the operating frequency and has gain over a
resonant dipole.

I had been wondering this myself.

I measured and cut a dipole for 3.75 cps(wish we still used cps) with a vf of .95.

Borrowed an analyser, it says lowest swr is at 3.49 Mhz/1.3, z=63 ohms, L=2.84 microHenries and C=717 pf.

The freq it was cut for 3.75 Mhz, swr=4.6, z=21, l-.925 microhenries and c=1990 pf.

Wire is multi-stranded copper clad RadioShack Antenns wire,feed with 50-ohm coax (used at this time for receive only, working on restoring a Tempo One I was given with 2 more as parts). The feed system will be changed when I get ready to use the radio..

So why would the SWR and impedance be better at a lower freq then it was cut for?

It depends on the velocity factor, the higher the VF, the longer the feedline. And you probably won't find a length that is exactly resonant on your favorite 75m frequency while at the same time is exactly anti-resonant on your favorite 40m frequency. Adjusting the feedline length is one method for tuning out reactance so it doesn't matter if the dipole is resonant on a particular frequency or not. I use my 130 ft dipole on all 75m and 40m frequencies without a tuner.

> On your web page you show some of the adjustable ladder stubs being
> loops. What about the main length? Does it have to run straight and
> be high in the air? Or can it lie on the ground snake-like (without
> crossing or loops coming close to each other)?

With my 130 ft dipole, the main length is about 80 ft and there is about 6 ft of overhead in my switcher. The ladder-line length selector is variable from zero to 31 ft so I can vary the overall length of my ladder-line from 86 ft to 117 ft in one foot increments. That allows me to cover all frequencies on all HF bands without a tuner with the possible exception of 3.5-3.6 MHz.

Don't put ladder-line or twinlead on the ground. It can be coiled snake like or hung accordion style but needs to be kept about six inches away from anything conductive including itself and the ground.

There are lots of variables. Make your measurements in free space
and see what changes. :-) An antenna can be resonant without
having a 50 ohm feedpoint resistance and its resonant resistance
will vary with height above ground. Virtually every wire dipole
is a "cut and try" rather than a "cut and dried" experience.

Reg, as promised I'm getting back to this:

Whether the apparent mistuning was *entirely* due to use of plastic insulated wire, I don't know. There were other factors, too. If my memory serves me correctly, the ARRL Handbook dimensions were for a single band quad, and the quad I built was a "spider"-type (no-boom) 3-band quad for 20-15-10 m.
Also, Handbook's dimensions may have been for a spacing of 0.125 WL btw. radiator and reflector while I chose to use 0.1 WL spacing for good match to 60-ohm coax we used.
The quad was atop an 8-store house, but not very high above the (tile) roof. The nearest cement floor was ca. 7.5 meters (or 24.6 ft) below.

Therefore, there were factors lowering loop resonances other than just wire insulation. Which factor contributed how much, I didn't try to find out.
This experience gave me a lesson though: *always* tune your quads - unless you replicate somebody elses design with *exactly* same dimensions and materials.
The fact remains that I had to shorten the loops by 5 %, and I'm convinced that wire insulation played a major part in the process. Other antennas I've built support this notion - but then you know what Kipling said...

My gosh chuck. You have an antenna cut for 80,000,000 meters!!!

I believe you meant kcps NOT cps!! [For us ol' timers it used to be cps not Hz].

Your lowest VSWR does not occur at resonance!! If the antenna is resonant there is no inductive or capacitive term!! An antenna does not have to be resonant or does not have to have a load impedance of 50 ohms to be an effective antenna!!

The "normal equations" are estimates because the effect of local earth/ground conditions and nearby objects such as trees and power lines seriously affect the antenna performance. If your antenna is in free space, [close to 2000 feet altitude with nothing within a 2000 foot circle] the equations will be close.

The term you list as "vf" at 95% is more correctly the effect of length to diameter ratio which directly contributes to the self inductance of the antenna wire. A non-parasitic antenna does not care about wire insulation. A parasitic antenna, such as a Yagi-Uda or a quad, does care because the insulation is in the excitation path for the parasitic elements and makes the path a dual capacitor [one with free space dielectric and the second with the insulation dielectric].

So, what do you have?? Answer, an antenna that is close to what you want and close enough to start trimming or stretching as required.

Thanks to all that replied. It does answer my question and yes, I meant 3750 kcps (KHz). Fat fingers missed pushing the M or K.

Yea, I need to trim and when I get ready for transmitting I plan on replacing the coax with twinlead and a tuner.

Have a good holiday and a good New Year.

How do you know? Maybe God doesn't roll dice. I don;t pretend to know the
answer to that one.

>Was it Schrï¿½dinger who said, "Not only does God roll dice, but
>He rolls them in the dark."?

Actually, I heard it was a description of a discussion of a thought experiment
involving Schrï¿½dinger's cat riding a surfboard on the crest of a wave made of
anti-photons. At least that's what somebody told me they recalled from a TV
show.

I believe he meant Mcps or Mc/s but that's beside the point.

> Your lowest VSWR does not occur at resonance!! <clip>

Would you care to elaborate on that, Dave? I seem to have believed that lowest (V)SWR _does_ occur at resonance. Any reactance due to non-resonant length tends to increase (V)SWR in a feedline.

It is, however, easy to confuse basic facts by measuring SWR at the *low* end of the line. In the words of someone who decades ago wrote in QST on measuring SWR: "A bridge can only measure what it sees." Usually we measure - not the resonance of an antenna - but the impedance at the "shack end" of the line which includes the transformer action of the line. Bridge imperfections add to the confusion - with the result that the antenna seems to be resonant somewhere else than the frequency it was cut for.

Otherwise I tend to agree with Dave.

5432. 40m dipole on 15 meters???

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-25 19:19:22 UTC
From: BICisfag <ll@jj.com>
Message-ID: <3E0A04BA.2393E6AC@jj.com>
Source record: 128370

My 40 m dipole seems to work as good as anything I have
on RX on 15 m.
It is coax fed but my 989 MFJ tuner won't tune the damn
thing very good at all.
Whats up with that. I thought it was a 3rd harmonic and should
tune easily.

5433. CAM? 80/40 m

Newsgroup: rec.radio.amateur.antenna

From: BICisfag <ll@jj.com>
Message-ID: <3E0A0840.D3FFD1F4@jj.com>
Source record: 128371

I have a seperate 80 and 40 m dipole.
I think I want to do a ladder line job to
make a combo 80/40 m dipole similiar to
what you did. (40 m dipole is too close to
where I'm going to have a beam)
80 m dipole is 125' long.
Can I solder 2 seperate lengths of 450 ohm to
80 m dipole (each 450 ohm length cut for 80 and
40), have a 1:1 BALUN on each of the 450 runs,
then coax into the house.
Then continue to use the antenna switch in the to
switch between runs.
Will this be about as efficient as what I have now?
Both are fed with coax now.
Can I lay the ladder line directly on the asphalt roof?

Will it be as broadband as what I have?

5434. Antenna Tuners & Active Antennae

Source record: 128372

My father-in-law (W9OIB) is in an assisted living facility. He likes to listen to what's going on on the bands even if he can't transmit. (I have him set up with an indoor random-wire antenna and there is a skilled nursing facilities with all sorts of monitoring equipment right above his apartment.)

He does not get very good reception, and I was thinking that the MFJ Active Antenna would improve his reception. My concern is that he tends to push the buttons on the front panel of his TS-450AT more or less at random and I worry that the small signal genertated by the antenna tuner might let the smoke out of the active components in the antenna. We have disconnected his microphone and key so he shouldn't be able to generate any signal stronger than that generated by the antenna tuner.

Can anyone out there offer any experience or advice?

Thanks,
Ed - N5KZW

Shouldn't need to tune it. I was quite happy in my novice days
using just a 40M Inverted Vee for both 40M and 15M.
Later -- with an Advanced Class ticket -- I completed 15M WAS SSB
with the same piece of wire.
Try it w/o any steenkin' tuner.

There is also a transmit button on the front of the transceiver for those folks that don't like to use semi-breakin or full-breakin for CW. If he presses that, he will get a full strength signal output depending on the setting for the output power.

It might be best to buy him a good quality shortwave receiver only.

Measured at the transmitter, I have seen the lowest 50 ohm SWR occur
where some reactance exists and the 50 ohm SWR be slightly higher at
the purely resistive point. It seems to happen under conditions where
the resistance is changing faster than the reactance.

5440. Re: How much difference does a resonant antenna make?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-25 21:35:00 UTC
From: whagen6@cs.com
Message-ID: <20021225163500.18487.00000265@mb-ft.news.cs.com>
Source record: 128379

a non-resonant antenna has reactance, which creates standing waves on the transmission line, and thus lots of energy is then stored in the capacity and inductance, which creates the standing waves. once this energy is built up, it then passes to the antenna and radiates. In a perfect world of no resistance in the line, all the energy would then be radiated, especially if the line is properly coupled to the transmitter. However, there is resistance in the line, and therefore the more energy the is stored there, the higher the voltage of the stored energy, thus the higher the current of the stored energy as it oscillates between the reactances of the line, and with a higher current there is a larger amount of energy loss due to increased resistive heating. This is lost energy and not radiated. Thus, a resonant antenna and a line matched to its impedance will be the most efficient, and non resonant antenna will be less efficient due to increased swr on a line, unless the line is matched to the impedence of the antenna and properly coupled to the transmitter.

You have the wrong idea. Ladder-line is added to the
92' 40m run to get the 110' 75m run.

> Then continue to use the antenna switch in the to
> switch between runs.

Use your switch to switch in the extra length of ladder-line,
not separate runs of ladder-line.

> Will this be about as efficient as what I have now?
> Both are fed with coax now.

You probably won't be able to tell the difference in efficiency
but the ladder-line without a tuner will be more efficient than
coax with a tuner.

> Can I lay the ladder line directly on the asphalt roof?

Not a good idea. Ladder-line should be kept about six inches
away from anything that has any conductivity. There may be
metal directly under the asphalt.

> Will it be as broadband as what I have?

My resolution is one foot increments so I don't worry about bandwidth.
Compare the bandwidths on my web page to yours now.

You left out feedline losses. Losses with open-wire 600 ohm transmission line
may be less with a "high" SWR than losses with coax in a matched system.

For instance, consider 100 ft of RG-58 feeding a 50 ohm dipole on 10m.
The loss will be about 2.7 dB. The loss in 100 ft of open-wire line with
an SWR of 10:1 on 10m is considerably less than 1 dB. You just cannot say
that "a resonant antenna and a line matched to its impedance will be the
most efficient".

I admit that, CAM. However, the usual case is the half-wave dipole or
derivations thereof, and reactance changes much more rapidly than
resistance, as a function of frequency. In _very_ small antennas, for
example, curious things may indeed happen.

Thank you for your remarks

You would even observe this at the antenna terminals, as opposed to at the transmitter end of the transmission line. Suppose you have a half-wave centre-fed dipole at a certain frequency. Its reactance is zero at that frequency and its resistance is a slowly increasing function of frequency, passing through say 60 ohms (making an assumption about its height above ground) at that frequency but a little less than 60 ohms below that frequency and a little more above that frequency. Meanwhile the rectance goes capacitive below the resonant frequency and inductive above it. To a first approximation both the resistance and the reactance change linearly with frequency, near the resonant frequency.

Make up some numbers consistent with the above comments. Take a Smith chart and plot the impedance as a function of frequency. You will see that as a result of the slowly changing resistive component, the graph is *not quite* tangent to the relevant circle and thus the minimum SWR occurs slightly off of the resonant frequency.

Of course in practice the effect is very small, but it is there.

>Prokek computer.

Two of the computers here in the shack have plain old radio shack
speakers, one of which has an additional base speaker. A third
computer has an amplifer and two speakers in the same cabinet. (the
kind that set under a monitor). None of the three pick up any
interferrence on any band 160 meter through 440 Mhz. I can fire up an
HT at 5 watts right next to the computers, or speakers and still have
no interferrence. However the computers make it a bit difficult to
hear any thing on 147.00 when the HT is close to them.

BTW, I run the legal limit on 160 through 10 meters, 100 watts on 6,
50 on 2-meters, and 35 on the 440 band.

Howdy, All

Some of the best antennas are NOT resonant. The 5/8 lambda vertical immediately comes to mind.

As a mobile antenna it has gain over a 1/4 lambda vertical which can be said to be resonant.

Put two of them together to get a 1.25 lambda doublet and you have an antenna which is not resonant and has gain over a 1/2 lambda dipole or a full wave doublet.

In short an antenna does not have to be resonant to do the job and some of the best antenna designs are not resonant.

yes you are absoltely right, thanks for pointing out what I left out. My arguement assumes only one type of line being compared with a resonant vs non-resonant antenna.
Because the resistance is so much higher in the 100 foot long 600 ohm line, the 10/1 swr loss is less because the current is less compared to the resonant 50 ohm system.
The system with the 50 ohm dipole, and 600 ohm line, the dipole being 50 ohms I assume is because it is resonant, thus having no reactance, wouldnt that be more efficient than say where the line was still 100 feet of 600 ohm line, and the dipole was not resonant, which would increase the swr due to increased reactance, or could the off resonant antenna be cut so the sum of resistance and reactance = 600 ohms, and be more efficient than the resonant 50 ohm dipole? Also, using a stacked dipole, which at resonance could be 600 ohms, wouldnt that be the most efficient system with the 600 ohm line?
And, here is a question that I dont have an answer to, maybe you can help me here, if the antenna is resonant and at 50 ohms, so no reactance, and one uses a halfwave length of 600 ohm line, so that the antenna impedence of 50 ohms is seen at the other end of the 600 ohm line, is there a swr of greater than 1/1 on the line?

Is it far to state that, a resonant antenna is always more efficient than a non-resonant antenna when the transmission line of the same impedence is used for both, or not fair to state because a transmission line can be found to match the impedance of the non-resonant antenna, and with proper coupling to the transmitter, will be more efficient? And, if the length is kept the same, the line that matches the non-resonant antenna would then have a higher swr with the resonant antenna, and would be more lossy, however if the length is not kept the same, then some length would transform the impedance to the impedance of the transmitter, and if it is true that there is no swr on a line length that transforms the impedance from the antenna impedance to the transmitter impedance, then wouldnt both a resonant and non resonant antenna have the same efficiency?

Source record: 128390

A 130 foot dipole is resonant on 3.6 MHz [1/2 wavelength], 7.2 MHZ [1 wavelength], 10.8 MHz [3/2 wavelength], 14.4 MHz [2 wavelengths], etc as long as it is an integral multiple of 1/2 WL it is resonant. It is a low impedance load on the 1st, 3rd, 5th and all odd multiples of 1/2 wavelength and high impedance on the even multiples of a full wavelength.

Antenna resonance is ANTENNA RESONANCE and is determined by the characteristics of the ANTENNA!! [Feed system is excluded].

A quick calculation, not rigorous, indicates that the antenna system is resonant and operating with a feedpoint VSWR of about 3:1 or a little higher on 3.6 MHz. Most rigs will easily achieve a match. [The unused transmission line [92 feet] introduces a shunt capacitive reactance across the load of between 160 and 200 ohms]. For 7.2 MHz the 110 foot line is 1 WL and reflects a high resistance on 7.2 MHz while the 92 foot line converts the high feedpoint resistance to a lower value. A quick non rigorous calculation indicates a feedpoint VSWR of 2.2:1 to 3:1 on 7.2 MHZ.

For those who are LOW VSWR addicts this is terrible!! But, it is a resonant antenna with a stub feed system that should work!!

Would I use it?? No! Too complex. I prefer a simple center fed doublet with tuned feeders.

5452. Vs: Vs: How much difference does a resonant antenna make?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-26 01:57:12 UTC
From: "Antti J. Huhtala" <oh2dt@sral.fi>
Message-ID: <audnl3fls1@nyytiset.pp.htv.fi>
Source record: 128392

OK, thanks, David. Always glad to learn something.

In my antenna & feedline programs I've used the following formulas for
getting at SWR:

ro = (Zl - Zc)/(Zl+Zc) ; for complex reflection coefficient ro

where Zl = complex load impedance (antenna) and Zc = complex characteristic
impedance of feedline.

From this

SWR = (1+ro)/(1-ro) ; where ro is the complex reflection
coefficient

The formulas become somewhat more cumbersome if impedances are written in
the usual (R+jX) form, and almost formidable if complex divisions are
written "out". A computer is just the thing for doing that.
Anyway, on the basis of the above, SWR will always increase if reactance is
added to a resistive (resonant) feedpoint impedance PROVIDED that the
resistive part remains the same. If it doesn't, a small shift in minimum SWR
will result.
The shift is, like you say, small, and does not explain why a dipole cut for
3.75 MHz should show a resonance at 3.49 MHz. Other factors are at play here
but they were already treated earlier.

Antii,

A center fed antenna one wavelength long is RESONANT but exhibits a radiation resistance of several thousand ohms and a VSWR, in a 50 ohm system, of > 40:1.

Resonance occurs EVERY 1/2 WL!! and is independent of VSWR.

As 'Hams' we think in terms of 1/2 WL antennas. But resonance is by definition that case when the radiation resistance is: Rr = R + j0. R can be any real [mathmatically real] value from 0.00001 to 100,000 ohms or any credible value.

My 20 meter mobile antenna has a radiation resistance of 18 ohms at 14.2 MHz. That is a true VSWR of 2.77:1. But at 14.05 MHz it shows a VSWR of 1.3:1. The additional capacitive reactance caused by the short antenna increases the apparent load impedance to something closer to what the transmission line wants to see.

5454. New simple LC filter design program

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-26 02:08:13 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <audoad$6tv$1@knossos.btinternet.com>
Source record: 128393

PROGRAM "LPF_HPF.exe"

Most filters consist of one or more cascaded, simple, 3-component, T or Pi sections and are used in a multitude of applications where pass-band ripple, frequencies of infinite attenuation in the stop-band, exact impedances matches, etc., are not of consequence.

This easy to use program calculates component values of high-pass, low-pass, T and Pi, basic filter sections. Internal filter loss is neglected. Operating inconveniences which may be present in more complicated programs can be avoided.

Filter response vs frequency is in terms of dB insertion loss between Ro terminations for 1 to 5 cascaded sections. Frequency range is from audio to VHF.

Download in a few seconds program LPF_HPF.exe from website below and run immediately.

5455. Re: 40m dipole on 15 meters???

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-26 02:16:44 UTC
From: Dave Shrader <david.shrader@attbi.com>
Message-ID: <3E0A664F.6030508@attbi.com>
Source record: 128394

It should if ...

1) it is resonant at or below 7.1 MHz
2) it is relatively free of surrounding obstructions trees etc.
3) it is relatively high
4) it is truly cut for 7.1 MHz or lower, not pruned to work on your
favorite frequency
5) the antenna load impedance is no longer ~50 ohms on 21 MHz it
increases to something in the 100 ohm range.
6) etc.

Conclusion: a 7.2 MHz antenna has a high feedpoint impedance with
significant reactance at 21.3 MHz. EZNEC calculates a VSWR of 7:1 at
21.45 MHz for a 7.2 MHz dipole.

So, a 7.0 to 7.1 MHz dipole will show a VSWR of 2:1 or greater in a 50
ohm system when operated at 21 MHz. A 7.2 MHz dipole shows a high VSWR
in a 50 ohm system because resonance is now 21.6 MHz.

All you need to do is attach a 6-10" stub at the 11' points either side of center and then trim them for best VSWR where you desire it on 15M.
Because the stubs are at a low Z, or hi current point on 40M, there will appear invisible.

5458. Re: How much difference does a resonant antenna make?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-26 02:54:20 UTC
From: Dave Shrader <david.shrader@attbi.com>
Message-ID: <3E0A6F1F.7040902@attbi.com>
Source record: 128398

Let's begin by defining EFFICIENCY.

Efficiency is the ratio of power output [radiated] to the power put into the system [out of transmitter].

There are numerous places where power is lost in an antenna system. Among these are:

1) the connectors carrying the RF have both ohmic and insertion losses.
2) the components of any antenna tuner
3) the attenuation factor of the transmission line
4) The VSWR and line construction
5) the insertion loss of any balun/unums
6) the loss resistance in the antenna
7) the losses in any traps or loading coils in the antenna
8) ground losses

At HF and VHF the normal 'Ham' connectors [PL 259/SO 239, Type N, etc] have minimal impact [typically less than 0.1 dB].

Antenna tuners, if used, typically have 0.2 +/- dB loss

3) and 4) have a major role in efficiency. Open wire parallel lines have extremely low attenuation factors. Coax lines have a loss factor that depends on electrical length and VSWR and this is higher than open wire lines.

Baluns and Unums have typically less than 0.1 dB loss.

Loss resistance in the antenna needs a little discussion. The antenna, resonant or non resonant, is composed of three resistive terms where power is dissipated. The first is the radiation resistance. This is the good stuff. We want this as high as can be reasonably achieved. The second term is the ac [rf] current loss resistance. This is higher than the dc resistance and is caused by 'skin effect'. An antenna using #12 wire will have a lower loss resistance than an antenna using #16 wire. Finally we have the end loss resistance across insulators etc to ground.

Ground losses, very real, would be constant in your analysis.

Notice that the reactance[s] are not included in this discussion. Reactances do not radiate or dissipate power.

So, an efficiency comparison of resonant and non resonant antenna systems is based on losses not on whether the antenna is resonant or not.

Efficiency is the ratio of power output to power input.

Sorry everybody, I forgot to use absolute value symbols in this latter
formula. It should be written:

SWR = (1+|ro|)/(1-|ro|)

Of course, the SWR on the 600 ohm line with a 50 ohm antenna will be 600/50=
12:1 which, on coax is relatively lossy but 12:1 on open-wire feedline is
usually acceptable.

> Is it fair to state that, a resonant antenna is always more efficient than a

> the transmitter, will be more efficient?

You've got to take everything into account. For instance, assume a resonant
folded dipole has a feedpoint resistance of 300 ohms. Using 50 ohm coax,
the SWR on the coax would be 6:1. Compare that to a non-resonant dipole
that has an SWR of 4:1. The non-resonant dipole will radiate more power
than the resonant folded dipole.

Back in the dark ages when I went to school at Texas A&M, we called
that the point of anti-resonance just to distinguish it from the
lower resistance resonant point.

Put up a fan arrangement and feed it with RG 58, 50 ohm coax. One pair
of legs 130 ft and one pair 66 ft. Just about any type wire can be used
for the antenna, even galvanized electric fence wire. Spread the legs
out away from each other.
You can use them to guy the pole by putting the 80 m set N-S and the 40
M set E-W.
The losses at 40 and 80 M are so low the wire and the coax can be the
cheapest stuff you can find!

I am in the process of purchasing a new home. There are some antenna covenants, but I should be able to live with them. The only real problem is now a single covenant that requires the developer to agree in writing to the construction of any structure including any type of antenna. I have been assured that this won't be a problem, but to have the agreement included in the purchase contract, they want to know what type of antenna will be installed. I intend to install some type of vertical, but have not decided exactly which one. (Any reccomendations?) Anyway to the point, they want something to asure them that I would not interfere with neiboring radio/TV and a set of descriptors for the proposed antenna. I am looking for something fairly generic that I could give them that would have the least impact on my ability to install/change antennas. I was thinking something like "I agree that my equipment will not cause undue interference with properly engineered equipment in the area. In all cases, FCC regulations regarding radio frequency interference shall be adhered to. Antenna will be .... (need the help here.) What do I need to change/add?
Help.

Reg:

Thanks for another great program!

However, as usual we are not privy to your methods of calcualtion. I was wondering???

Does your program use the simple, venerable, but approximate, image parameter design formulae?

If not then perhaps you are aware of, and have been delighted by, the remarkably simple explicit
formulae for the exact element values of low-pass, all-pole, ladder filters with Butterworth and
Chebychev characteristic functions. These remarkably simple formulae involve only the trigonometric
functions powers and square roots, and may be executed easily by hand on a scientific calculator.

As a "teaser" the extremely simple formulae, known as Bennett's formulae, for the "normalized" element
values of the N'th order Butterworth [a.k.a maximally flat] minimum inductor, low-pass characteristic
function operating between one Ohm source and load resistances [R1 = R2 = 1.0 Ohms] with exact
unity passband ripple bandwidth and exact passband attenuation ripple given by Ap in dB are:

Ck = 2 eps^(1/N) sin(Pi (2k-1)/2N)): N - odd
Lk = 2 eps^(1/N) sin(Pi (2k-1)/2N)): N - even

Where: eps = sqrt(10^(Ap/10) - 1.0) is the passband ripple factor with Ap in dB.

No need to calculate poles and zeros, no need to understand complicated Butterworth and
Chebyshev polynomials, no need tolearn how to read tables and nomographs nor to exert
the effort to carry them around! The results, unlike image parameter design, are exact and
are not approximations.

Apparently Bennett "discovered" the remarkable Butterworth formulae long ago, and it was many
years later, and with great difficulty, that Takahashi "proved" the formulae and introduced several
new ones for the Chebychev case including some predistorted designs.

A table for the element values for the 5th and 6th order filters operating between one
Ohm terminations with 3dB ripple at unity bandwidth can be generated by hand on a modern
scientific calculator in moments. Here's a table for Butterworth filters which I generated by hand
in a couple of minutes.

N C1 L2 C3 L4 C5
5 0.6180 1.6180 2.0000 1.6180 0.6180
6 0.5176 1.4142 1.9319 1.9319 1.4142 0.5176
N L1 C2 L3 C4 L5 C6

Of course the conventional simple element by element reactance transformations from low-pass to high-pass
and low-pass to band-pass along with frequency and impedance level scaling may also be easily executed by
hand on a modern scientific calculator.

As with your program, ideal elements are assumed, and consequently the effects of finite Q of the elements is
not accounted for by these formulae. However, there exists simple algorithms, derived from sensitivity analysis
by Mayer Blostein Gabor Temes, which I have used for many years, which estimates the effects of semi-uniform
element value losses and termination mis-matches on the passband response.

Although I use a calculator myself, I have long felt that such exact formulae could form the basis of a very
elegant and simple "Reg Edward's style" program for all-pole insertion loss filter design. Such a program
could also readily handle the denormalizations from unity bandwidth and impedance levels to the practical
final desired targets as well as the conventional reactance transformations for high-pass and band-pass cases.

If you are interested in more information on these remarkable formulae for the Butterworth and Chebychev
characteristic functions, there is a nice description of them with an outline proof along with 13 references to
the original literature in:

Louis Weinberg, "Network Analysis and Synthesis", McGraw-Hill, 1962, [see Ch. 13, Sec. 13.5]

There is also a write up on how to use them effectively in:

Adel S. Sedra, and Peter O. Brackett, "Filter Theory and Design: Active and Passive", Matrix, 1978.

Enjoy!

Season's greetings,

Scott, the ANTENNA does not cause interference.

I would state:

"The amateur station, including antennas and supporting structures, will be in complete compliance with the requirements of 47 CFR 97.1 - 97.527.

For the purposes of this document a particular reference to paragraph 47 CFR 97.121a is included by reference."

I would pick up a copy of Part 97 from W5YI or equivalent source, take the time to become familiar with it and have it available for reference.

FYI: 97.121a is the paragraph that states among other items "If the operation of an amateur station causes general interference to the reception of transmissions from stations operating in the domestic broadcast service when receivers of good engineering design, including adequate selectivity characteristics, are used to receive such transmissions ... " Then silent hours are imposed. Also, subparagraph b allows for FCC investigation of complaints.

Build your terms based on complying with the normal Federally imposed requirements for your station.

Examples: telephone interference, VCR interference, computer sound card interference are excluded because they are NOT receivers of the domestic broadcasrt service and do not exhibit "adequate selectivity". Once the legalities are defined then good neighbor practices should be followed. I keep about $200 of telephone filters, clamp on ferrite beads, and various chokes that the owners can connect to their equipment externally.

Good advice.

I would also not limit yourself by defining the antenna you might erect. Rather, limit you antenna to 500 square feet or whatever, to allow some flexibility in the future. don't say "Cushcraft" or whatever,because you can paint yourself into a box.

And in the agreement, make THEM agree..not you. Make the developer affirmatively state what you can do. That way there is no question.

> I was thinking something
> like "I agree that my equipment will not cause undue interference with

How much intereference is "undue?" What is "properly engineered?" Stay away from language like this. JMO.

And, whetever you do, get a good real estate lawyer to handle this.

Jeff

Al, W6WQC wrote:
"You may want to click on "Antennas and Feedlines"---."

Why a non-resonant length? A feedline with SWR can provide "just as good a performance".

Al, that is hyperbole!

Al wrote: "The definition (1/2-wave) has nothing to do with current magnitude."

More hyperbole!

The link between antenna length and current into the antenna is a match to the feedline. A conjugate match maximizes power transfer and antenna radiation. A feedline which looks like Ro transfers maximum power into an antenna feedpoint of Ro.

Al is just generating another old wives tale that length doesn`t matter.

Best regards, Richard Harrison, KB5WZI

Source record: 128417

Here is the question for the enlightened:

We know from the tuned circuits and RF transformers that the higher the Q, the sharper the tuning and coupling efficiency.
Projecting this into antenna situation, where antenna is the transducer between RF in the wires and RF in the space.
Can we increase efficiency of this transition by any means?
Is high antenna Q of any benefit to make it more "sensitive" to RF extraction from the space?
What about matching the space impedance (377 ohms) with antenna impedance?
One thing we know the capture area of the antenna (array) is one factor.
Another factor is the terrain (shaping the pattern) and ground conditions (altitude, ocean).
I have not seen much elaboration on this subject in the (limited) selection of literature I had the chance to read. Is this non-important or overlooked subject? Any pointers to books or web pages?

From: Richard Fry <rfry@adams.net>
Message-ID: <aufae7$6mavk$1@ID-175933.news.dfncis.de>
Source record: 128418

An antenna with an "infinite" return loss at its feedpoint already radiates as much power as it gets. The only ways to increase field strength for a given receive location, time, frequency, and antenna input power are to modify the radiation patterns of the antenna, and/or set up a propagation path having less loss.

Richard Fry

Source record: 128320

Kevin:

[snip]
> I would be interested in the explicit Chebychev LC solution. Could you
> post it?
:
:
> Kevin Aylward
[snip]

Yes, I will do that, but only as a Christmas Gift to the NG.

The Chebychev case is rather more difficult to render in email/NG format and
so
due to egg nog, etc... I cannot be held responsible for errors during my
typing
or transcription errors. Please consult the original references for
corrections.

i.e. There is a No Return policy on this gift post.

With due credit to the great H. Takahasi who discovered several remarkable
novel
properties of the Chebychev polynomials, provided a proof of Bennett's
formula for
the Butterworth case, proved that the Butterworth characteristic function is
a limiting
case of the Chebychev characteristic function [as eps approaches zero!] and
discovered
and proved several new and unique explicit closed form element formulae for
LC ladder
filters:

H. Takahasi, "On the Ladder-type Filter Network with Tchebyshff Response, J.
Inst.
Elec. Commun. Engrs, Japan, vol. 34, no. 2, Feb, 1951. [In Japanese!]

Note, I use the email/NG equation posting protocol found at:

http://www.karlscalculus.org/email.html

First use the ripple factor

eps = sqrt(10^(Ap/10) - 1.0)

where Ap in dB is the passband attenuation at the bandedge to calculate an
intermediate
constant h

h = [(1/eps) + sqrt(1 + (1/(eps)^2)]^(1/N)

to obtain the more interesting quantity zeta

zeta = (h - 1/h)

The element values for Chebychev low-pass ladder filters are then given iteratively by the
following remarkable iterative formulae:

C1 = 4*sin(Pi/2N)/zeta*R1

C(2k-1)*L(2k) = [16*sin((4k-3)/2n)Pi) * sin((4k-1)/2N)Pi)]/(zeta^2 + 4*(sin(2k/N)Pi)^2

C(2k+1)*L(2k) = [16*sin((4k-1)/2N)Pi) * sin((4k+1)/2N)Pi)]/(zeta^2 + 4*(sin(2k/N)Pi)^2

for k = 1, 2, ... N/2.

The end elements are also given by

C(N) = 4*sin(Pi/2N)/zeta*R2, for odd N, or

L(N) = 4*R2 sin(Pi/2n)/zeta, for even N.

so that the formulae may be used in the reverse direction as well which is required for the
even order case to determine the correct termination resistance for maximum power
transfer, i.e. zero insertion loss.

Here's some worked out examples to help y'all understand these remarkable formulae...

I will calculate the element values for the 3rd and 4th order Chebyshev filters with
pass band ripple Ap = 0.1 dB, unity cutoff frequency, and source resistance of 1.0 Ohms.

Here Ap = 0.1 dB so that eps = 0.1526204 and eps^2 = 0.0232930

For the 3rd order Chebychef filter ---

Here, with h = 2.36215 we calculate zeta = 1.938812, and with R1 = 1.0 Ohms...

C1 = 4 sin(Pi/6)/zeta = 1.031560 Fd.

C1*L2 = [16 * sin(Pi/6) * sin(3Pi/6)]/[zeta^2 + 4 * (sin(Pi/3))^2] = 1.183609

L2 = 1.1473966 Hy.

C3 * L2 = [16 * sin(3Pi/6) * sin(5Pi/6)]/[zeta^2 + 4 * (sin(2Pi/3))^2] = 1.183609

C3 = 1.031560 Fd.

For the odd order Chebychev the filters have a reflection zero [attenuation zero] at
zero frequency and so the termination resistor always equals the source resistor

R2 = R1 = 1.0 Ohms.

For the 4th order Chebychev filter ---

h = 1.905378, zeta = 1.380548, R1 = 1.0 Ohms...

C1 = 4 * sin (Pi/8)/zeta = 1.108787 Fd.

C1*L2 = 16 sin (Pi/8) sin (3Pi/8)/[zeta^2 + 4 (sin(pi/4)^2] = 1.448280

L2 = 1.306184 Hy.

C3*L2 = 16 sin (3Pi/8) sin(5Pi/8)/[zeta^2 + 4 (sin(2Pi/4))^2] = 2.31240

C3 = 1.770351 Fd.

C3*L4 = 16 sin(5Pi/8) sin(7Pi/8)/[zeta^2 + 4 (sin(3Pi/4))^2] = 1.448280

L4 = 0.818075 Hy.

Since this is an even order Chebychev there is no reflection zero [attenuation
zero] at zero frequency and so the termination resistor R2 for zero insertion loss
is different from the source resistor R1. To determine the termination resistance
the filter is partially sysnthesized from the other end as follows to obtain L4 in
terms of R2 as...

L4 = R2 * 4 * sin(Pi/8)/zeta = 1.108787 * R2 and thus R2 can be calculated
from the two values of L4 by the ratio

R2 = (L4 from the left end)/L4 from the right end) = 0.8188075/1.108787

R2 = 0.737811 Ohms.

Undoubtedly y'all can appreciate the convenience of these explicit formulae,
especially for simple Reg Edwards style programs. The network elements
are obtained directly with no computation of poles and zeros or extensive
polynomial manipulations.

For more on such formulae including predistorted designs and impedance
transforming filters see:

H. Takahasi, "On the Ladder-type Filter Network with Tchebyshff Response, J. Inst.
Elec. Commun. Engrs, Japan, vol. 34, no. 2, Feb, 1951. [In Japanese!]

Scott, I've heard of some developers removing restrictions after they have developed and sold all the houses in the track. I've always thought this meant that they were more concerned about the antenna appearance, which may have an impact on their ability to sell houses, rather than the interference it could cause to equipment in houses already sold. I'm wondering if the comment about interference is something that the sales agent is telling you as he or she may not really know why the developer want's to approve all new structures.

If most of the houses around your new house have been sold and if the antenna is a ground mounted vertical rather than a beam on a 50' tower, I wouldn't think you would have much of a problem.

[snip]

Unless Cecil comes riding in on his EM wave to make changes to commonly
accepted theory,
such interactions would only be observed in the "near field" where "return
currents" exist.

In the "far field" the photons [radiant energy] are essentially
disconnected from the source
and do not interact with the circuit oriented phenomena in the source that
emitted the energy.

Although circuit theory is derived as a subset and an approximation from the
more
complete wave theory, the circuit theoretic approximation involves the
complete
absence of radiation from the circuit theoretic models. The impedance
of space [377 Ohms] is a wave theoretic phenomena [Ratio of E to H fields]
and has essentially no relationship with circuit theoretic phenomena [Ratio
of V to I].

To the extent that EM theories are complete, the "impedance" of space and
the

"impedance" of a circuit are in two completely separate domains of influence and
never directly interact.

The acceleration of electric charges in a circuit, causes the creation of photons and the
complete release/escape of radiant energy from the circuit carried off in those photons.

From the circuit theoretic view, this loss of energy [radiation] is observed/felt as a
resistance in the circuit, i.e. the radiation resistance, and not the impedance of free
space.

It is unfortunate that we use the same name [impedance] for the ratio of the electric
to magnetic fields as for the ratio of voltage to current. And they do have the same
units! But just because things have the same units does not mean that they are the
same or comensurate. For example the voltage across my car battery divided by the current in your flashlight has units of resistance but it is not a resistor.

There are lots of examples of this re-use of terminology in technology that often
leads to mis-understandings. The whole area of reflected power is rife with similar
misleading uses of terminology.

Q does not lead to coupling efficiency, it follows from it. Both are victims of the same factor, Iï¿½R loss. Hi Q is not very useful if you are trying to get power out of the antenna - do you want to save it or spend it? Even the vaunted final's tank works best at a Q around or less than 10. The difference here is in the subtle distinction of loaded and unloaded Q. The load should swamp any Iï¿½R issues and there is your statement of efficiency. Thus it follows that you are looking for an unloaded Hi-Q and a loaded Low-Q from the same design. How anyone could measure the unloaded Q of a dipole is left for you to work out. ;-)

>Projecting this into antenna situation, where antenna is the transducer between
>RF in the wires and RF in the space.
>Can we increase efficiency of this transition by any means?

The common halfwave dipole is already quite efficient, unless, of course, you choose to bury it in the ground.

Nearly every treatment and discussion of the antenna seems to divorce its roots, the transmission line, from its matching aspect.

First, consider what we call current lobes or nulls. If we were looking at a transmission line we would call them SWR. The standard halfwave dipole is also known as a Standing Wave antenna for good reasons. We already accept that the antenna is loaded by the ï¿½ther and by abstraction, that load is at the end of the tips of the dipole standing at a value of 377 Ohms. We observe a value of 72 Ohms at the interior connections of those same tips, ï¿½ wave away.

The dipole can also be thought of as a Quarter-Wave, non-linear, leaky transmission line terminated by a high Z (377 Ohms). The characteristic Z of this transmission line varies in the same direction of wire spread, but as a Quarter-Wave match it should exhibit an average Z of 166 Ohms. The correlative to this argument is found in the conical dipole whose geometry employs a linear, leaky transmission line concept. By further correlation, the conical dipole is more widebanded and thus lower Q'ed than the thin wire dipole. Any boon in efficiency improvement is probably lost in the decimals.

Hi Yuri,

I covered this tangentially in my analysis of the fractal antenna.
One page is dedicated to their 377 Ohm Antenna Z across very large
bandwidths:
http://www.qsl.net/kb7qhc/antenna/fractal/Wide%20Band%20Comparisons.htm

The price to achieve this performance is found in the scope of the
design, specifically in the 64 meters of wire required to support the
"flat" matches across the higher HF frequencies. I treat the
radiation issue separately, but I would offer 9 - 12dBi in a perfect
world; unfortunately, not in a direction that would be intuitive from
the physical design of the antenna (no boom to clue us in).

Peter O. Brackett wrote:
> Unless Cecil comes riding in on his EM wave to make changes to commonly
> accepted theory, ...

I'm not making changes to commonly accepted theory, Peter, I'm just reminding folks what was the commonly accepted theory in the 1950's before virtually everyone was seduced by the shortcuts inherent in the steady-state model. Or as my Texas A&M professor put it, "Unless one is dealing with DC, there is nothing steady about the steady-state model". I was taught that the steady-state model is a bunch of mathematical shortcuts that work but have little to do with what is happening in reality.

In particular#1, waves moving in opposite directions in a fixed Z0 lossless transmission line have no effect on each other. They pass each other "like ships in the night".

In particular#2, a virtual impedance cannot be the cause of anything since it is just an effect of a V/I ratio. I am amazed at the number of otherwise knowledgeable RF engineers who believe that a shorted 1/4WL of lossless transmission line blocks any RF energy from flowing into it because it exhibits a virtual impedance of infinity. Here's that stub.

x------1/4WL lossless T-line---shorted
Now apply a signal:

Signal Generator-----x------1/4WL lossless T-line---shorted

Do the reflections really occur at point 'x' because the virtual impedance at point 'x' is infinite? Or do the reflections really occur at the short because the short is really there?

Hi Peter,
Happy Holidays to you and bunch!

Assuming my flashlight is connected to your battery and has incandescent lightbulb, I was taught that it is resistor with resistance. What's wrong with that picture?
If I connected to my battery can I call it resistor? :-)

I see what you are saying about two different domains and terminology.
So I gather that our first goal is to efficiently kick them photons off the wire into the space (low losses in feeders and antennas). So besides that there is not much we can do to make the space (atmosphere) to "suck" them photons more efficiently than we are presently doing?

What about curtain arrays (and rhombics), with larger apperture, aren't they providing better coupling to the space? Antenna modeling software does not account for coupling to space, and some people dump on them, but those who built and used them have (anecdotal) feeling and "evidence" that thay play very well.

Then, disregarding propagation properties, is there any appreciable difference in having antennas at low grounds, vs. being very high in the mountains (thinner air)?

Yuri, K3BU wrote:
"Can we increase the efficiency of this transition by any means?"

Radiation efficiency is achieved by making radiation resistance high as compared with loss resistance which heats the conductors and non-conductors of the antenna and its environment.

No antenna is truly non-directional, so it is more effective to have tne antenna`s most favored directions agree with the desired directions of communications.

In space wave communications, polarizations of the electric fields of the sending and receiving antennas need to agree.

In sky wave communications, the vertical radiation angles of sender and receiver should match.

A good book to confirm the above is Ed Laport`s "Radio Antenna Engineering"

Best regards, Richard Harrison, KB5WZI

Well, coupling effciency would be between the antenna and space. Let's say it what it is - constant (for particular situation). The Q of the antenna is not just I2R losses, but referring to the physical properties of radiator - thin wire (within reason) has higher Q (narrow bandwidth) thick tower structure has lower Q (wider bandwidth). That is the (RF) Q I am looking at.

I am trying to digest the points.
One think that keeps popping in my mind is the statement of K8CFU, who did some measurments on the verticals and found that folded dipole had "surprisingly" more FS than just straight monopole.

We know that and about shaping the beam, but what I am questioning, is there way to improve "kicking" off photons from the wire to the space, the coupling between the antenna element and the space environment. Like if I heated the wire red hot (using Peters battery :-), would that help?

A stub is a piece of transmission line that acts either like a
capacitor, inductor, open, or short. You can use a capacitor
or inductor instead of a stub. But I guess real hams use stubs. :-)

An isotropic radiator does not exist in the physical world, but many antennas designed for commercial FM and TV broadcast transmission are omnidirectional in the horizontal plane (+/- a few dB), over a fairly wide span of elevation angles.

It should , using the tuner. I find it hard to believe that that tuner won't match that. I have the same tuner, and it will match nearly anything. You must be passing the proper settings up some way. I just checked my 40 meter dipole on 15m. The SWR was over 2:1 at 21.300. My tuner matches that no problem at all. The inductor was only at 2-3 turns from zero. Meter is flat on the peg. Dunno, me thinks you are not tuning carefully enough, or using the wrong methods to find the correct spot in tuning. BTW, that tuner will match a load at usually many settings of the knobs. But only the one using the least inductance to get a usable match is the correct setting. MK

5504. Re: What is a Stub? Re: 40m dipole on 15 meters???

A transmission line 'stub' is a length of transmission line that is open or shorted at one end. It is effectively a capacitor or inductor, depending on length, and can be used to achieve a match [VSWR = 1:1] if connected at a selected point in the basic transmission line.

Example:

```
| Antenna
Transmission line |
--------------------|---------| VSWR > 3:1
VSWR 1:1 |
|stub
```

Designing stubs requires a knowledge of the reflection coefficient and how to use a Smith Chart. The length and location of the stub achieves a conjugate match at the stub location and the transmission line is 'flat' from there to the transmitter.

There are solutions for single stub and double stub matching. Note, stub matching is optimized for one frequency only, or a narrow band of frequencies.

Provided that an antenna has no ohmic loss, the "coupling efficiency" --
as you're using the term -- is 100% for any antenna: all the power
applied to it is radiated. You can't improve on that. Unless you're in
an antenna manufacturing marketing department. Sorry, there's no free
lunch or magic bullet.

Of course, the efficiency of any antenna can be improved by reducing the
ohmic loss, but for a lot of common antennas, the possible improvement
is negligible.

No, that won't have any effect at all at the "coupling efficiency" as Yuri is using the term. All it'll do is reduce the ohmic loss. If you're using a full size dipole, Yagi, quad, or a host of other antennas, you wouldn't be able to tell the difference (except in your refrigeration bill).

Not so. A 10 wavelength dipole fed with 100 watts doesn't couple even a milliwatt more power into the air than a half wavelength dipole does.

Egad, the lack of fundamental understanding of conservation of energy is deeper than I thought.

Reg, G4FGQ wrote:
"What would you suspect if the antenna appears to resonate slightly higher in frequency than expected?"

Answer: A mistake in measurement or construction.

Reg also wrote:
"How would you determine the frequency of the antenna anyway without leaving the shack?"

Answer: Target characteristics of the antenna are needed. At resonance the antenna should match its feeder.

Minimum reflected power represents the resonant frequency of a matched antenna.

A VHF ground-plane antenna with (4), 45-degree drooping radials, several wavelengths above earth fits the description of an antenna which should match 50-ohm coax at resonance.

An antenna admittance or impedance bridge can be used to determine impedance from the shack and this will be the antenna impedance if the feedline is 1/2-wavelegth.

An antenna noise bridge (mine is a Palomar) can be balanced for minimum noise detected by a receiver to determine antenna resonance without leaving the shack. Again, a 1/2-wavelength feedline would be helpful. The calibrated dial of the receiver indicates the frequency.

Best regards, Richard Harrison, KB5WZI

Okay thank you all for your input on this.

In hindsight I should have been a bit more specific with the question.

The next part is (hopefully) going to maybe you think. Lets forget about the antenna being used for transmitting and concentrate on receiving. One of the "gurus" in my local 2M ragchewing group maintains that for receive a resonant antenna makes a huge difference. His answer to my doubts were "go and try it".

I'd like to get your feedback on his statement...

==========

Indeed it does work essentially way with any impedance line.

Unfortnately, changing the line impedance COMPLETELY changes the very limited set of frequencies at which it is possible to obtain useable values of resonant frequency and low SWR in HF amateur bands. You have shown that only 290-ohm feedline works.

Its a law of nature that at least TWO adjustable knobs are needed on any antenna tuner. You have only one - that which changes line length. The knob which adjusts line impedance is fixed at 290 ohms which by chance happens to work. Good for you - you discovered it!

Change amateur band frequencies and you have to change line impedance at the same time keeping your fingers crossed.

Yours, Reg, G4FGQ

How big is the surface- is it prime focus or offset fed?
It might be useful for 10GHz terrestrial or AO-40.

Source record: 128356

CQ! Please can you help me? Do you recognise this HF amateur mobile antenna by it's description?

It has a huge chromed sprung base, slightly cone-shaped, on top of a round black circular insulator, fitted on to a chromed mounting plate, with J-bolts (for bumper mounting?). It has an SO-239 socket below.

The sprung base is then topped by a chrome solid section about three-quarters of an inch in diameter, and about 3ft in height, which ends in a grooved collet constraining a chrome knuckle-fold hinge joint (in effect, giving the option to drop the whole antenna to half-height, I assume, to allow a vehicle to drive without spiking birds). This section reminds me of a mike stand, and it has a small captive plate drilled-out at this knuckle-fold to allow two support tielines to go back on to the vehcle body.

This big pole section is then followed by a *huge* grey plastics bi-cone centre trap, 3/8ths threaded top+bottom, with three variable capacitor and coil sections, each of which is adjustable from outside, and marked beside each access hole I, II and III. There is a central perspex inspection ring, to see these beefy components.

The very top of the antenna is clearly meant to be a whip (which is missing), so the overall effect is a centre-trap multiband collapsable HF/low VHF mobile antenna. Very good build quality, but not anywhere near milspec Shakespeare etc

My questions are: what make/model/vintage is it? What band(s)? How long should the missing whip be? What maximum power? And is it as good as it looks? This antenna is a very rare sight over here in the UK, so I would appreciate any help anyone anywhere can offer.

Wilf, Scotland

It depends upon the antenna impedance you are trying to match. The
WWII ARC-5 transmitters had only one tuning knob for the military
during wartime. They set the frequency and then adjusted a single
series inductance.

> You have only one - that which changes line length. The
> knob which adjusts line impedance is fixed at 290 ohms which by chance
> happens to work. Good for you - you discovered it!

I discovered a lot of other things also, Reg. The feedpoint impedances are
more reasonable when the dipole is 1/2WL on the lowest frequency of operation.
The resulting feedpoint impedances tend to describe a spiral on a Smith Chart
throughout the entire HF range of frequencies. Most of those impedances lie
within the doughnut described below.

> Change amateur band frequencies and you have to change line impedance at the
> same time keeping your fingers crossed.

Of course, some planning is in order. One can use EZNEC to estimate whether
it will work or not. Set the SZ option to whatever Z0 you intend to use and
run EZNEC on that dipole for all bands of interest. If the SWR is between
3:1 and 12:1 for 300 ohm twinlead, between 4.5:1 and 18:1 for 450 ohm ladder-
line, and between 6:1 and 24:1 for 600 ohm open-wire line, you can match it
to a 50 ohm SWR of less than 2:1 by varying the length of the feedline. And
of course, one needs a guard band to account for variations.

Here's another way. Write down the feedpoint impedances provided by EZNEC
for all the bands of interest. Take a Smith Chart and draw two circles,
one through 25+j0 ohms and the other through 100+j0 ohms. That will give
you a doughnut on the Smith Chart. Plot your antenna feedpoint impedances
on that chart. If the antenna impedance is inside the doughnut, then the
antenna can be matched to a 50 ohm SWR of 2:1 or less by varying the length
of the feedline.

There are an infinite number of antenna impedances inside that doughnut, Reg.
Why would you not be satisfied with matching an infinite number of feedpoint
impedances without a tuner? Why would you ever need to match more than an
infinite number of feedpoint impedances? :-)

It sounds sorta like the Hustler antennas. The mount is separate from
the antenna. IOW you could purchase the antenna and then put what
ever base under it you wished (as long as it was strong enough)

I don't know if they are still made but back in the 70s they were
quite popular.

In the early 70s I had one on my car. I used a straight bumper hitch
with the antenna mounted and a base insulator mounted directly to the
hitch.

You could fold the antenna over and lay it down right on the roof of
the car for going into the garage, or parking ramp.

The top sections, called resonators were a loading coil and whip
combination. The early loading coils covered the pre WARC bands 80
through 10.

As to dimensions, "If we are talking about the same antenna" were
about 1/2, or 5/8ths inch base section with the collet and hinge. As
I recall the base section continued a couple feet above the
collett/hinge, where the top section screwed on. The fitting was in
the bottom of the loading coil.

I'm planning on using an 11 foot C-band dish, which also works on KU
band for 2.3 Gig
The vast majority of C-band dishes will also work on Ku, with the
exception of the mesh dishes that have the *large* openings, or holes.

You'd probably want to use an As/El mount instead of the polar mount
if considering EME. For EME you'd probably want a dish on the order
of 12 feet or larger. Point to point the standard polar mount, with
the elevation lowered to 0 would work, but it is difficult to get the
larger dishes mounted very high at they are both heavy and have one
whale of a wind load. It takes a pretty big support to get them above
20 feet.

The smaller dishes can be side mounted on a tower for point-to-point
up in the 10 Gig range.

==========

Infinite number of feedpoint impedances? The trouble with your system is that you don't match ANY of them!

Planning using EZNEC and Smith Charts takes a month of Sundays. The sunspot cycle won't wait for ever. ;o)

Use program DIPOLE3 and you can do the job as fast as you can write down the list of resonant frequencies and associated dBs. Line loss and overall efficiency also come out in the wash.

I did some investigating many months back. So far as I can remember I found 300-ohm gave most useful dB results but, as might be expected, efficiency was not too hot. 600-ohm did not provide a sufficient number of suitable within-band selections.

But I prefer to use SWR=1.5 as the highest acceptable SWR.

I would not accept SWR's as high as 2. Although a manufacturer may honestly say his transmitter will not blow up with an SWR of 2-to-1, power output begins to fall off almost as soon as the SWR meter needle shifts off the stop. It's the reactive component of the transmitter load which is the main culprit.

(Incidentally, G5RV resonance occurs in only one band unless you juggle with line impedance - as might be expected it's 20m).

Never be without program DIPOLE3. Obtain it without delay from website below -

It could be one of the Swan 742 antennas which later became the B&W
370-19. These antennas operated on 75, 40 and 20-meters. They are
described as looking like a Midas muffler. I also seem to remember an
antenna coil that was tear-drop shaped (like an airfoil) that covered
10, 15, and 20-meters. May also have been in an ARRL handbook many
years ago.

My IC-706 starts folding back at 15W reflected. When it is putting out 100W,
that's an SWR of about 2.3:1

> (Incidentally, G5RV resonance occurs in only one band unless you juggle with
> line impedance - as might be expected it's 20m).

I have seen a G5RV resonant on 80m, 40m, and 20m. Of course, the resonant
frequency on 80m was 3.6 MHz.

> Never be without program DIPOLE3.

If EZNEC and MicroSmith were not second nature to me already, I sure wouldn't.

My 130 ft dipole receives just fine on all HF bands. I don't even know
exactly the frequency on which it is resonant. Perhaps your friend is
getting "matched" and "resonant" confused.

Most of our receivers have enough automatic gain to compensate for
any loss of signal in the antenna system because usually noise is
reduced by approximately the same amount as the signal is reduced.

But you just said HF, where atmospheric noise will always be the problem in resolving a low strength signal. What about in a VHF/UHF environment where front end noise is more of a problem? Every erg of signal getting to the radio front end will be important.

The cruncher with the main question is why do we bother even analysing antenna reactance? We can do all of our tuning with just an SWR meter?

ARRRRRRRG! The biggest disservice to amateur radio is the SWR meter. A dummy load has a good SWR, Does it get out very well? SWR only shows that you have a good match to a system, not if it (the system) is or is not efficient. Without a tuner to make my transmitter happy, my antenna has neither a low SWR or resonance on any frequency I operate.

5538. Dipole balun test findings

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-27 22:53:56 UTC
From: Stagger <stagger3@yahoo.com>
Message-ID: <7NudnTXsxJHbRJGjXTWc2Q@comcast.com>
Source record: 128277

Hi, I know you guys probably seen a ton of these questions, but I was doing a little test. This is what I found....

If you were constructing a dipole without a balun, you would connect the center conductor to the top pole, and the shielding braid to the lower pole.

I checked my balun with a continuality meter to see what side matches up with the center pin. I found continuality on both output leads from the center pin. Same as for the threaded shield side.

I though the way a dipole worked was by having opposite and separate polarities? If I used a balun, it would seem both the center conductor and the shield would be going to the top pole. And the same for the bottom pole.

Can anybody shed some light on this finding?

Thanks in Advance
Stagger

It's probably a voltage balun and if you check the schematic in your ARRL
Handbook, you will see essentially a DC short between all contacts.

For 14' and smaller polar mount offers distinct advantages over AZ/EL- including simplicity, cost and, within reason, pointing accuracy. The VK3UM tracking software supports polar tracking- in particular the configurtion I presented at 2001 SEVHF Conference. That paper is available in their compendium, or I can send it as a Word document- about 2 meg as I recall.

Don't confuse DC continuity with the way RF "sees" the balun.

And, if balanced, it will not matter if you connect the center conductor to the top or bottom radiator.

That's just what you should find!!

In simple terms a balun has two windings connected together at the
center tap {coax}. The end of one winding connects to the center of the
coax. Transformer action then induces an opposite polarity in the other end.

It's a simple statement. Design and construction techniques have to
ensure close coupling of the inductive path and minimal capacitive action.

>The cruncher with the main question is why do we bother even analysing
>antenna reactance? We can do all of our tuning with just an SWR meter?

Yes and no. When I was a Novice 35 years ago I did all of my tuning with a #47 lamp tapped along my xmission line and tuned for max brillance. Didn't need an swr bridge nor did I own one. I couldn't figure how to hook the 50 ohm swr bridge into the 300 ohm twin lead I was using.
These days, I dabble in antenna design, especially physically short, loaded and mobile antennas. Knowing the R+/-jX of the antenna feedpoint is quite important to me. Could I get the antennas going with just an swr bridge, yes, but I would not like to try. An antenna analyzer and a Smith Chart make matching experimental antennas a snap.
If you know your antenna "system" is close to a 50 ohm match to your xcvr, then a 50 ohm swr meter should be all you need for tuning. With VHF/UHF antennas, these are usually full size designs commercial, or out of a book or formula. A 50 ohm swr bridge might be all you need.
The 50 ohm swr bridge has limited use, as defined by whom is using it.

Wilf:
I can assure you that is not the description of any of the models which Newtronics made under the Hustler name. I no longer recall the details of the Swan antenna, but I do recall that it was a complex monster. The plate for the stays strikes a familiar cord. About 1960. Probably designed for 200 watts AM, so it should handle the legal limit on SSB in the UK. If your principal interest is recovering the information on the length of the top whip, it was likely about 50", as that seemed to be the norm back then. Only the individually constructed "bug-catcher" installations exceeded 8 feet in overall length for practical and safety reasons. If you have the bottom portion of the antenna, bolt it on your vehicle, get an 8' "CB" whip with removable base, screw it into the top of the coil and start cutting and measuring.

5547. Station Earth / RF Earth for shack on 2nd / 3rd floor

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-28 01:25:24 UTC
From: Martin <Martin@_NOSPAM_g1gyc.demon.co.uk>
Message-ID: <auiv4t$f10$1$8300dec7@news.demon.co.uk>
Source record: 128286
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.misc,uk.radio.amateur

Hi, and thank you for reading this.
I am in stalling my radio station in to the small "box room" on the 2nd floor
of the building and I have in the past not worried about a separate earth for
the station. But as this station is going to be a more permanent arrangement
than my other previous locations I want to make sure that :-
1) the station is safe electrically. (of course the supply earth will be
connected)
2) protected form static (lightening etc).
3) has a good RF performance. (this means low resistance earth connection)
4) is as clear of EMC problems as possible.

So any one got some pointers or helpful hints on installing a separate station
earth. The ground connection is easy 3 to 6 off 6' long 1" dia copper pipes
driven all the way in to the soil (I know it is a big is job but not
impossible).
The bit I am puzzling over is do I use a heavy copper strap as used on church
lightening conductors to provide a common earth for every thing or just for the
static protection and then a separate heavy conductor to provide the shack
equipment earth.
In either case how can I ensure that the earthing does not radiate RF (I assume
that making sure the aerials are correctly balanced with suitable baluns fitted is
the answer here.)
I did here about using RG8 type coax and connecting both inner and screen
to the hardware in the ground but only connecting the shack earth buss to the
inner - any thoughts on this.

Cheers Martin

Try this: K0FF design (not circular, but SQUARE) and also has 6 meter
version.
both posted on web. 2 meter version at:
http://www.hamuniverse.com/loop.html

6 meter version at: http://www.qsl.net/k4pwo/sloop.htm

Both made of copper tubeing, and solder together!

Hope this helps, jim NN7K

I would say a resonant "system" , not a resonant antenna . Even then,
all you are doing is pumping up the S meter, unless the level drops so
low that internal noise masks the desired signal. "VHF". Otherwise the
s/n ratio stays much the same. But for VHF, it gets more complicated
as you have to consider decoupling of the antenna to the feedline.
This will have a larger effect on performance than simply having a
better match from the line to the antenna. Many antennas are not
resonant in themselves, but still have gain over a 1/4 GP, or a
dipole.
Look at the feedpoint of a 15 el yagi. It's not a good match to coax
until you add a matching device. A 5/8 GP is not resonant until you
add a loading coil to tune to a 3/4 wave resonance. But a 5/8 radiator
will still have the same pattern matched or not. So unless signal
level is an issue, matching with the loading coil is not required for
just receiving use. The problem is on VHF, signal level vs internal
noise is often a problem. If you have a high SWR, feedline losses that
coax will usually have in the VHF range, will eat you for lunch. But
on HF, this is much less likely to be a problem just for receiving.
The antenna does not need to be resonant on VHF to perform well. All
you need is efficient matching from the antenna to the line being
used, and good decoupling. So in a sense, the antenna is resonant as
far as the load at the end of the feedline, but only due to the use of
a matching device. A multi wave long rhombic is not resonant. Have
him compare one of those to a "resonant dipole", or GP on VHF and see

which wins.

Bob, tis not that simple, as for best reception (as in "Noise Figure, or Factor), of a reciever at vhf, the front end is Intentionally MIS-TUNED for the BEST SIGNAL/NOISE ratio! assuming a 50 ohm antenna, and coax, rarely will the R.F. stage of the reciever will have a 50 ohm impedence! Has to do with the noise generated in the r.f.amp dropping faster (or more), than the signal does, and allows reception at smaller signal levels. For the reasoning, need to consult with weak signal engineers like N6CA, or others that design low noise preamps-- jim nn7k

5554. Balun for helical antenna at 2.4 GHz ---- help!

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-28 04:53:37 UTC
From: Tasos Zafeiropoulos <abc@panafonet.gr>
Message-ID: <aujapchcf1@nic.grnet.gr>
Source record: 128293

I want to make a balun for my helical antenna at 2.4 GHz...

Can anyone help me out? Is it a good idea to use a L/4 coaxial cable to match the impedance?

If yes, how can I can fit it in the antenna?

Any suggestions woul b appreciated..

Greetings
Jim, duth.gr

<< This big pole section is then followed by a *huge* grey plastics bi-cone centre trap, 3/8ths threaded top+bottom, with three variable capacitor and coil sections, each of which is adjustable from outside, >>

Wilf-

I recall seeing advertisements for a mobile antenna that might fit your description, in QST back in the 1950s. I think the antenna was made by the E. F. Johnson Company, maker of the Viking series of Ham rigs. Could your antenna be that old?

If it was possible to cover all bands with just those tuning components, the length of the top whip couldn't be critical. If you have something that fits, try it.

There is a real nice how-to on Eham.net right now about that.
The story is called "6 & 2 Meter Square Copper Dipoles" and
can be found at http://www.eham.net/articles/4319 I found it
very interesting and helpful, also has some great photos of the
work in progress.

It's likely that your house wiring is on a system called PME, in which case it's vital that your external earth is connected to the house wiring earth at the meter panel. I'm sure there will be IEE wiring regs on how this should be done. You might also try to get your hands on an article called 'The Killing Fields' by Peter Chadwick, G3RZP. It was in RadCom a good many years ago.

If you have a PME system you also need to ensure the earth bonding point where the supply enters your house is bonded by 10mm2 wire to your local earth rod(s). This is especially important if your power comes via overhead cables. You can usually get to the bonding point next to the power company fuses.

If not, under certain fault conditions a LOT of currrent can try to pass via your shack to earth. Not good.

> 2) protected form static (lightening etc).

Static isn't too difficult- use DC grounded antennas on VHF/UHF and provided a 'bleed path' via a choke or even a resistor for HF antennas.

You can get devices to protect against lightning but having seen the effects of lightning tests I don't think I would trust a cheap one. I always disconnect.

> 3) has a good RF performance. (this means low resistance earth connection)
> 4) is as clear of EMC problems as possible.

These often go hand in hand.

For VHF/UHF the problems are generally resolved by using good coax, connectors, sensible antenna siting, and filtering (as required).

For HF, given the likely problems of a earth lead impedance at HF, I recommend an external ATU- either a SGC (or similar) automatic beast or a remotely variable arrangement. The latter need not be overly complex- a simple LC arrangement, L either switched with relays or a roller coaster with a small motor (a cheap electric screwdriver is ideal) and a motorised capacitor(s). I can look out a circuit I did for someone else if you like- he want something cheap and cheerful and I think the motorisation cost him

about £10! I works very well, if I ever get around to HF myself I may build one.

To get a good RF earth you can run out radials from the ATU, the more the better. These should be bonded to an earth rod at the ATU. A buried 'earth mat' is nice but not always practical.

The above approach tends to keep the RF 'in' via the coax and equipment casing until it get to the ATU which, as the latter is remote, minimises coupling to other equipment.

Once the RF gets to the antenna it may still cause EMC problems- but that is down to the fact it is radiating, which it is meant to do ;-) Then it is down to filtering to minimise harmonics etc. and coupling into domestic items.

The most common helical- helix+ reflector, is an unbalanced antenna and
does not require a balun.

How big is your (back) yard? means how big is the rear garden to your house if you have one?

Here in the UK we have been using "metres" as a measure of wavelength ever since Hertz.

And since we joined the European Common Market (Due to be renamed the USE just as soon as Blair can get himself promoted to president. At present he is taking lessons from Bush), all has gone metric except beer which is still measured in pints rather than litres because we havn't yet broken all our 1 pint glasses.

Only United States Citizens are still living in the measurements age of Ancient Brits, bodies all painted with purple woad (mud).

Who's interested in what's reflected?

Like everybody else, you should be interested in what power is being
RADIATED when the SWR is not 1-to-1.

And that begins to fall off well before the ALC takes control.

I agree. Long ago, I designed low noise vacuum tube amplifiers for use
in radio astronomy. (I have a big binder somewhere that contains about
all that was known about that art.) For best SNR, one does not use a
conjugate match. See volume 18 of the MIT Radiation Lab series.
(Written before transistors, but contains all that one needs even
today.) The most embarrassing moment of my life came when, in the
middle of a lecture by my mentor John Kraus, it was casually mentioned
that the front-end was to be matched to the antenna - I blurted out that
that was not so, and quickly tried to smooth things over. Right after
the lecture, I rushed to my room and wrote a short paper showing why,
then went back to the department and slipped the paper under Kraus'
door. Nothing more was ever said.
As I get older, the urge again arises to blurt things out.
Fortunately, my reflexes have also slowed down (grin).
As a practical matter, with the very low noise amplifying devices of
today, the difference is not great.

Well is that so? Add yourself a bit of extra earthing and bond it to the PME - I think NOT!

Both Peter Chadwick and I, who've had previous discussions and agreement on this would profoundly disagree with you!

PME, where the neutral has a disconnection somewhere outside of your property has likelihood to pass huge amounts of current, and hence a rise in potential down and to any local earth you might provide or have in your home. It is a cheap but dangerous way to supposedly provide an electrical earth.

The answer is to provide yourself with some good quality ELCB's (30ma if possible) at your shack and home. Provide yourself with a good quality earthing system which is tested to current standards and when this is done disconnect the crappy PME system.

And yes I have seen the effects of a disconnected neutral with PME, which has resulted in persons receiving shocks as well as interference to electrical equipment

From someone with Experience! Who has his PME disconnected and that's the way it's staying!

==========

Yes, that's me.

Unfortunately, Cec, when the SWR meter comes off its end stop there isn't
100 watts to start with.

Because of the incorrect load on the transmitter the output transistors get
hotter and output power falls off well before the (delayed)ALC takes matters
into its own hands.

To analyse performance of your system the PA protection features can be
ignored.

But in any case analysis is reduced to guesswork because you don't know the
internal impedance of the transmitter. If anybody says 50 ohms resistive I
shall scream and scream and scream! ;o)

From: Glynn Kevin <kfglynn@mindspring.com>
Message-ID: <aukq86$65k$1@slb2.atl.mindspring.net>
Source record: 128316

Hello everyone,

I was wondering what kind of balun you use on your dipole and/or other wire antennas.

I've used RG-213 coax chokes wound on 2 liter coke bottles as well as W2DU Unadilla 1:1 bead baluns with success. I'm in the process of making new antennas and was curious to what others were doing.

The plan is to have single inverted-v dipoles for 10 and 20 Meters, with a 40 Meter zig-zag dipole for 40 and 15 Meters or just a 30 Meter dipole (not sure on the 3rd one yet). BTW Doug DeMaw W1FB (SK) once told me on the phone that the coax chokes would work as well or better in my environment. TVI/RFI potential is huge where I live. A contester measured coax chokes and felt using 4" PVC as a form was superior to the W2DU bead baluns (6 turns for 20 Meters and up, 12 turns for 30 Meters and below). The feepoints will be about 9 feet above the roof with the coax coming off down to the roof, then running off the flat roof down to the window. I was thinking about a choke at the roof edge too, in case currents were being picked up by the shield on the coax.

Thanks for the input, I appreciate it.

I don't have the training to determin the outcome and I understand that the mismatch is needed for the lowest noise figure. The only other thing is how much differance it will make in the aditional feedline loss not to have a good match to the coax. Where is the tradeoff between the matching and mismatching as to the total noise figuer of the whole system from the antanna to the preamp ?

5579. Re: Balun for helical antenna at 2.4 GHz ---- help!

Source record: 128317

Tasos,

It depends on the twist, but the one I once built had a feedpoint impedance
of about 100 Ohms, unbalanced. So, you would use a 1/4 wave section of 75
ohm coax to match to 50 ohms. If the impedance is near 200 Ohms, use a 1/4
section of 93 Ohm (RG62) coax. I would bring the coax out behind the
reflector; mount an N connector on the reflector, and solder the helix to
its center pin.

The rise is potential is dependant on the resistance of the bonding lead.
The local electricity company recommend 10mm2 as being adequate for the
job. I assume they would know- the engineer I spoke to knew all about the
problem once I mentioned what I was concerned over.

> The answer is to provide yourself with some good quality ELCB's (30ma if

The local electricty company advised against this method - especially in
situtions where there was a real risk of the neutral disconnection, eg in an
area supplied by overhead wires. (It is extremely rare with buried supplies
they tell me.) In fact, they advised they would disconnect my supply if I
used it this method.

>
> From someone with Experience! Who has his PME disconnected and that's

OK, but if you local supply company don't like it you may well get
disconnected.

Using RG-400 teflon coax cuts down on the cost of the toroids. I have
measured the effectiveness of a number of balun/chokes and found a
W2DU type using RG-400 and ten FB-77-5621 cores is very effective,
more effective than ten turns of RG-400 on an FT-240-61 toroid.

Dear Ralph:
I should have made clear that the NF in a receiving system, using modern components, hardly ever is significant below something like 25 MHz. (Off the top of my head, I can only remember one civilian receiving system operating in upper HF where NF was of concern.) In modern times, the effective SNR is determined outside of the receiver in almost all cases below about 25 MHz.
As many have said many times on this news group, at HF (and below) almost any piece of wire will "work." SNR can be improved by use of an antenna with a directivity (not necessarily gain) that suppresses undesired signals and enhances desired signals. For receiving, the transmission line, as long as it does not pick up undesired signals or undesirably distort the antenna's directivity, has almost nothing to do with SNR.
[I may have left out some of the assumptions.]
Above HF, loss in the transmission line adds noise (while attenuating the desired signal) that can be noticeable. In one UHF system with a short, solid transmission line from the antenna's feed to the first amplifier, I once considered a scheme to cool the transmission line in order to reduce the noise introduced by the line. This was not a terrestrial system. ...wrote a paper many years ago about the effective extraterrestrial noise picked up by a highly directive antenna pointed a bit above the horizon (at VHF and above).
To your question: For modern terrestrial HF receiving systems: unless the antenna has a very small "height" (incident E times height = volts), the issue is inconsequential. (A very short antenna, presents many issues.) A large ratio of transmission line surge impedance to nominal receiver input impedance might reduce the apparent signal enough to bring the receiver's NF into significance.

In short: have the two just mentioned impedances be in the same ball park.

I knew that for anything below about 30 mhz the NF was not too important as most any modern device will have a low enough NF as not to worry. My main thainking was at frequencies around 150 mhz and above where a typical ham might run around 100 feet of coax with a loss of 1.5 to 3 db when matched. While a preamp mounted right at the antenna will have a lower NF when mismatched, my thinking was that we get some aditional loss in the coax due to a mismatch. My thinking was if the mismatch would result in a swr of 2 or 3 to 1 the aditional loss would be so low as not to be noticed and you gain due to the mismatch. However if the mismatch was 10 or 20 to 1 the aditional loss might make the overall NF of the system worse.

At my last QTH I did exactly as you describe and it worked well for many years. I also disconnected the earth pin on every mains lead for my rig and linked all the chassis together with coax braid.
I'm not sure of the legalities of this, but what nobody knows, nobody worries about. Good luck.

Dear Ralph KU4PT:
Ah! 150 MHz. Perhaps I am finally in the right church. Sorry to
have gone on about HF.
I think that I understand your concern. [Mind, I may still not be
near the right pew.] Your concern is that the "mismatch" that optimizes
the receiver's NF might reflect (very small pun) an additional loss that
would tend to negate the benefit from the "mismatch."
Not to be concerned. The "mismatch" with modern components is
expected to be too slight to effect a noticeable additional loss.

Sorry that it took an iteration for me to get close to the subject.
Once upon a time, most every class had at least one perceptive student
who would ask your kind of question. Of course, at that time, at least
a few of every class would be radio amateurs. I have got out of
practice. Thanks for continuing.
It is also nice to see a call sign. Too often, that nicety is left
off.
Keep asking questions.
73, Mac N8TT

Ralph, for all intent and purposes you are correct about 30 mHz and lower. in fact, as terrestrial noise peaks at around 50 mHz (6 meters), the bragging rights for converters, preamps, ect. in "anchient times" (early 1960's thru late 70's) was more sales pitch, than practicality. for a tower mounted preamp, at 2 meters, with only a slight mistuning on the INPUT (not effecting the output, tune for max umph) the only consideration for the preamp (apart from being able to withstand transmitting power with change-over relays) is to have enough gain to overcome the coax loss, AND the noise figure of the reciever (combined) to maximize your reception (apart from the bandwidth of your reciever (gain 6 dB in sensitivity every time you HALF your reciever bandwidth. S= 4ktRB , if memory serves me correct, Sensitivity = 4 X temprature in o 's Kelvin, X Boltzmans Constant X Reciever Bandwidth). For preamp at the reciever, the swr for the input of the preamp will be so slight as to be next to nonexistant as far as multiplying loss's because of swr.

Thanks for the reply Mac. When you mentioned radio astronomy I assumed that you ment vhf and above and not around 18 to 20 mhz for Jupiter. I have noticed that 6 meters seems to be the worse band around here for noise of all kinds. About all that is worse is when I fire up the computer in the ham shack and get s9+20 db of noise right on the calling frequency for ssb.

I do play with some 144 and 432 weak signal stuff. Have built a gasfet preamp for 144 mhz out of the handbook a few years ago and also have one for 432 but they are both in the shack. Just too much trouble for me to add all the relays and tower mount the preamps for the playing I do . Also I would have to duplicate that as I have antennas setup for oscar on another short tower. Have about 100 feet of 9913 type coax for both bands and that was really the reason for the question. Most people only look at the swr at the transmitter end, but on receiving I also think you have to look at it from the antenna end going back to the receiver to get the aditional los due to the swr. I know that if the swr is low or the line has a very small loss the swr is not too important to signal loss but it can be a big part of the loss if the swr is high and line loss is high. I usually send a signal out of a service monitor to a small antenna and try to adjust the preamp for the best S/N ratio as I don't have a good way to actually measuer the NF. That sets the whole system for maximum s/n instead of adjusting the preamps with the signal generator plugged into the preamp. I was just courious as to the differanc in what would hapen if I did have the equipment to do the checks.

I am comparing it to other antennas I have used on 40 meters, including dipoles, verticals, and 1/4 wave slopers. I have used baluns on some of those antennas, but never could detect any difference in performance with or without one.

My loop works fine without a balun. If you choose to use a balun as a matter of course, great. Have you ever tried comparisons with an without a balun? How many dB of improvement have you observed with a balun?

<< The loading coil/cap was called the "WHIPLOAD-6". >>

Cecil-

I dug through some old boxes and found my 1955 ARRL "Radio Amateur's Handbook". In the E. F. Johnson advertisement section in the back, I found reference to two antenna loading networks.

The one I was thinking of, is called "Bi-Net". It is a dual band loading network for ten and twenty meters. It mounts in the center of a "standard" mobile whip for completely automatic band change while in motion! Catalog number 250-22, Amateur Net $10.95.

This one is streamlined, with a tear-drop shape when viewed from the top. According to the ad, the size is 4-7/16" X 5-5/16" X 2-3/8".

The other one is the "Whipload-6". It appears to be cylindrical. The ad doesn't mention its size, but from the photograph, I imagine it might be like a small coffee can.

According to the ad, the Whipload-6 provides high efficiency base loading for mobile whips with instant bandswitch selection of 75, 40, 20, 15, 11 and 10 meters. On 75 meters a special capacitor, with dial scale, permits tuning entire band. Covers other bands without tuning. Air-wound coil provides extremely high "Q". Fibre-glass housing protects assembly. Mounts on standard mobile whip. Catalog number 250-26, Amateur Net $19.50.

I wonder if either of these match the one Wilf has?

Baluns do not add nor usually detract from your antenna perfomance, they do however eliminate RFI...that is the main purpose of your basic 1:1 balun...the others are used to match input/ouput...and really do help. search a little deeper, and you will find a wealth of value in baluns, as well as many ways to NOT use them. 73 K5MDM

Roy,

If you are asserting now, as Murray did, that RFI is eliminated by use of a balun, I don't find that claim in your article. You do mention the frequently cited "TVI caused by a nearby radiating feedline", but in what percentage of RFI problems is that the cause? I suspect the most RFI comes from antenna radiation, not feedline radiation. A balun has no effect on that.

I always thought a balun was intended to facilitate the connection of something BALanced to something UNbalanced. There are situations where we would want to do that. That part IS pretty simple. But curing RFI is rarely as simple as adding a balun.

73,

Roger K6XQ

> that.

I have no idea how many RFI problems are caused or aggravated by radiating feedlines. But in my limited experience, I've found that common mode currents on conductors such as power cords, telephone lines, or speaker cables are most often the means of ingress of RF into consumer devices. And exactly the same techniques described in the article are effective in eliminating common mode currents on these conductors.

Feedlines often run much closer to house power and telephone wiring than antennas do. So relatively small common mode feedline currents can often couple a considerable amount of RF into house wiring. In cases where this is the coupling method, a balun will help.

>
> I always thought a balun was intended to facilitate the connection of
> something BALanced to something UNbalanced.

Yes, I mindlessly repeated this phrase for many years without having any idea what it really meant before I finally decided to try and understand just what is meant by balance and unbalance, exactly what it is that's balanced or unbalanced, why or why not it might be desirable to use some kind of device to transition from one to the other, what the consequences would be of not doing it, and how one could evaluate how effective a balun is at doing whatever it is they're supposed to do.

With the single exception of Walt Maxwell's article (referenced at the end of the Compendium article), I couldn't find any answers among the large volume of published material. The result of my search for understanding was the the Compendium article.

There are situations where we
> would want to do that. That part IS pretty simple.

Indeed it is. So isn't it surprising that until Walt's article nobody bothered to explain it, and that many balun articles were written which told in great detail how to measure various properties of baluns that have nothing to do with the characteristics they need to have in order to be effective?

But curing RFI is
> rarely as simple as adding a balun.

Again in my limited experience, adding a common mode choke (or, as the term is used in the article, a "current balun") to appliance leads does often cure a household RFI problem. But I certainly agree that a great number of RFI problems aren't solved by this technique, and more yet aren't solved by adding a balun to an antenna transmission line (which is actually your point). No single technique is always effective.

The reason I always use a balun is simply that I want my antennas to act predictably, with respect to pattern and impedance, and don't like them to be sensitive to feedline length and placement or the length of the wire from my rig to the Earth. I'm also not fond of the idea of losing power by running my feedline along the ground. But many or most hams could care less about these considerations and so do just fine without baluns. Others are occasionally annoyed by "hot" microphones or other undesirable effects and fiddle with feedline lengths until the problem is reduced to a tolerable level. That's fine too.

> Have you ever tried comparisons with an without a balun?

Yep, back in high school I burned a hole in my lip from my
metal microphone. My ham mentor told me to coil up my coax
outside my window and tie the braid to a ground rod. My
RF-in-the-shack problem went away. My present 450 ohm
ladder-line fed dipole has five times as much common-
mode current without a choke as it does with one.

I ran one in El Paso Texas a few years ago and encountered
more hecklers than participants so I just salvaged the equipment.
Cecil came over and was a big help he may have more to offer.
The California group that did a several shoot-outs seems to have
stopped since Jessie moved to the Pacific Northwest.

If you do a Google Groups search you should find results from the
California events. Bottom line the best thing center coil loaded with
extensive top hats. Screwdriver types down just 1-2 dB. Worst
performers my Outbacker on a mag mount and Cecil's CB whip
with a SGC tuner. Hamsticks and Hustlers are a bit better but
nothing matches the center loaded designs. The one exception
was a Texas Bugcatcher style that was constructed out of
stainless steel, what a dog even my Outbacker outperformed it.

Cam:

My balun-less loop exhibits no RFI or RF in the shack, even running close to a KW output power. So I don't have a problem for a balun to cure, I guess.

That may not be the case for all antennas, and in some cases a balun will help. In other cases a balun won't make any difference.

When I put up the loop I had planned to use a balun. I wanted to first prune the loop to resonance, check the SWR, then install a balun. I was even looking into possible designs for a balun with a 2:1 impedance transformation so I could replace the 1/4 wave length of 75 ohm coax. But the antenna's performance seemed fine without a balun. It showed no measurable reflected power at resonance and had a wider SWR bandwidth than any other 40 meter antenna I have used, so I decided to leave well enough alone.

73,

Roger

Message-ID: <yeFP9.72618$Nz5.2064399@twister.austin.rr.com>
Source record: 128252

I am using a great filter design software package called Elsie from WB6BLD available here

http://mywebpages.comcast.net/tonne/software.html

The software allows me to tune component values then graph the final filter results. The filters I plan on building will be used for receive only and will be a LP with a cutoff at 500kHz and a HP with a cutoff of 1700kHz. The filters will be placed just before the receiver at the antenna input. I'm having various problems with the AM band that I want to eliminate. Can I use molded chokes for the inductors? To come up with close to exact values, can I parallel the molded inductors or will this cause too much coupling problems? What type of inductor would you recommend?

Thanks for all input.

Always thought my labtop modem and cordless phone were consumer-grade junk until I choked my feedlines. Now I run a kW without bothering either.

The simple fact is, common-mode chokes do exactly what they are proported to do. I've verifed this concept by attaching sensitive clamp-on RF current meters to a 15-meter coax-fed dipole strung 7-feet off the ground (meters on each leg and one on the feedline). I used barrel connectors and short patch cables to vary feedline length and used clamp-on #43 sleeves to choke the coax (or not) at the feedpoint. If you want dramatic proof, try it yourself.

I found that isolating the outer surface of the shield virtually assured balanced (symetrical) current distribution on the horizontal radiator regardless of feedline length or far-end termination (grounded vs. floating). On the other hand, when the coax wasn't isolated by a choke, current symetry was variable--anywhere from excellent to awful--depending on the impedance the "third wire" (shield) presented to the feedpoint.

Needless to say, when the feed began to rob current from the intended radiator, mucho guano began to happen. For example, the radiator's resonant frequency tended to shift off its predicted point, the antenna's driving impedance began to change, the cable surface tended to radiate RF (and--by reciprocity, pick up noise when receiving), and the pattern shape became perturbed. However, beyond all these effects, probably the increased level of ambient RF energy appearing at the operating site poses the greatest "real-world" problem for operators.

In most antenna installations, the load presented by the outer surface of the shield is difficult to predict because there are simply too many variables in play. So why dub around? Isn't it better to install a choke at the feedpoint as a matter of good engineering practice and be done with it?

Hello Martin are you in the UK or some other part of the world. There are 3 items of elevated earthing that need to be addressed. Any mains operated RF equipment must have an efective electrical earth, which is not the same as an RF earth. Any RF earth lead, dropping from an elevated shack, could be a significant portion of a wavelength, so you really ought to decide what bands you are expecting to work. It is not difficult to solve once you know the pitfalls.
If you are in the UK have a look at your electricity meter instalation, and see if there is a label marked PME or Protective Multiple Earthing, if you are in a high rise block you may need to make further inquiries as many were wired in that way.

Bill
Check your cable TV supplier they may supply an FM signal on the cable system, alternatively
Do you have any walls that line up with the wanted stations + - 45 degrees, or are broadside on to the wanted transmissions, especially if they are dry lining type walls. One idea that has been successful is to construct either yagi type beams, or broadside arrays, out of tinfoil (Cooking foil) or the burglar alarm tape you stick on windows.
You construct the antennas by cutting and pasting it on the wall (tacking care to ensure electrical contact at any joints) when it is finished you simply wallpaper over it

Just a thought.

Has anyone ever installed a mains isolating transformer or two
and run the shack items off of that ? The idea being that those
shack items can then have their chassis connected to an 'RF'
garden-style earth rather than the household mains earth - there
being no direct connection between the two earths.

Cheers,

Gareth.

Al,

I think you are trying to reject the broadast band. Have you thought out the configuration. You can't put the filters in series. If you put them in parallel, you have to be careful about how you couple them. For instance, if the LPF is capacitor input, it will short the input to your HPF. When you run the software to graph the filters, do it with both filters connected.

Generally people put inductors in series. If by molded inductors you mean the things about the size of 1/2 W resistors, they are fairly low Q, and will result in a lossy filter. The inductors in your LPF will have lots of resistance. For receive, that might be OK. It would be cheaper and better to wind your own inductors on toroidal cores.

I suspect you will get lots of comments on this one.

This can get very dangerous if it is possible to come into contact with the 'mains' earth in the house, and the 'shack' earth simultaneously. Any difference in potential can be quite uncomfortable, and under certain conditions might be fatal!

If you go down this road, make absolutely sure that nothing that is earthed on the house supply, or any metalwork, pipes etc is anywhere near anything in the shack. Something as innocent as vacuuming out the shack (not that I ever have) could prove nasty if you have one hand on the vacuum cleaner and the other touches your radio gear...

I had my earthing checked out after I got a surprise one day while standing out in the garden and reaching through the kitchen window to turn the wireless up. Funny buzzing sensation... I measured about 95 volts between mains earth and a spike stuck in the lawn! Turns out that all my wiring and earthing is all OK according to qualified people, but personally I'm not convinced. I just treat 'inside' and 'outside' as two very different places. I'm not sure how the 95 volt potential is developed as I'm not on PME here, even though it seems like the kind of thing that happens when PME goes wrong!

Dan.

Yes, a local does that. Only potential (no pun intended) problem is ensuring you can't readily contact anything grounded to the PME - such as the CH pipes or any equipment in the shack not connected via the isolating transformer.

Unless you have an RCA.. It took a choke on my RCA power cord to kill off some 6 meter TVI. The set was hooked to cable TV but even with the TV coax unplugged and hooked to a vcr I still had tvi tuil I inserted a choke in the power line.

==========

Roger, the intentions are good, perhaps a little misdirected or mistimed.
But I admit it is sometimes difficult to rein in one's horses. On other occasions you may be held down, your nose pinched and the pills forced down you.

As for my own experience, in more than 20 years living in densely populated areas, I have never had a TVI problem which was cured by inserting a choke in the transmitter feedline. I once had a case where inserting a choke in the TV antenna downlead solved the problem and another case where inserting chokes in a Hi-fi equipment speaker leads was sufficient.

In the 3rd and last case I did nothing on my side of the garden fence. The next door door neighbour's TV was returned to the dealer who discovered that on a previous repair he had fogotten to replace the lid on a screening box which housed the IF amplifier.

Finally, it goes without saying, practically all radiation emanates from the antenna.

Tam, thanks for the reply. I worded my question poorly. I plan on using one filter at a time. If I listen to LW, then I will insert the LP filter. If I listen to the HF band, then I will remove the LP filter and insert the HP filter. In either case, I hope to block the AM band from causing interference.

Yes you described the molded inductors I had in mind. I did not realize their Q was so low. I was hoping to get a handful of these and experiment as to which works best. I'm not daring enough to calculate and wind my own. Is there some other source of inductors, ready made, that I could experiment with for this project?

Thank you.

Hi Gareth,

I do this for my battery charger (a laboratory grade linear power supply) and run off batteries. However, I still connect the two grounds together, at the ground rod.

I am not particularly bothered with the prospects of lightning, not in the Pacific Northwest (we have the lowest incidence of lightning strike in the 48 states). However, I do still maintain lightning safe practices like a one point entry window for all RF and electronics which is tied to that same ground rod (less than 10' away).

Having an isolation transformer can be turned into an illusion of isolation very easily through the casual connection of one piece of equipment that has a ground path (somewhere). Do you have an outboard DSP that uses a "brick" power supply? Ground may be busted DC-wise, and yet it may be a conduit for noise from the Mains. How about a computer connection for packet? Does the computer have a modem attached to a phone line? How about one of those premium SWR meters with backlights and digital displays - again, plugged into some anonymous wall-wart power supply? The opportunity to violate the isolation is exceedingly easy to come by and simple to implement.

Another point, the isolation transformer is good at decoupling of RF and noise, but it is not an RF ground buster. You do not separate the two grounds, except by the DC and low AC path. At HF, it is a must that you have two good grounds otherwise the transformer turns into a very large coupling cap. By the nature of good transformer construction (which includes a Faraday shield), both grounds are figuratively strapped together for RF. The greater virtue of an

isolation transformer is it allows you to extend the "balanced" metaphor where it counts: at the source. It also lets you choose which ground as being superior for your situation.

Gareth Rowlands wrote:
"Has anyone ever installed a mains isolating transformer or two and run the shack items off of that?"

Yes. Countless times. At several hundred commercial installations, the 230-volt mains fed a ferroresonant voltage regulator transformer (Sola) which supplied a 500-watt transmitter/receiver combination. Also, in one location, (8) 50-KW shortwave transmitters, each had its own Sola, 7-KV in and out, 50-Hz, 3-phase mains transformer.

Isolation was not used to provide separate earth connections for primary and secondary circuits. This is usually a bad idea. A unified ground connection is needed for safety and performance. Primary and secondary circuits were bonded in all cases.

Best regards, Richard Harrison, KB5WZI

Al, KA5JGV wrote:
"Is there some other source of inductors, ready-made, that I could experiment with for this project?"

Old radios, surplus vendors, etc. Low-pass and high-pass filters can come ready-made from coil suppliers such as: J.W. Miller, Barker & Williamson, R.L. Drake, The William Nye Co, Radio Shack, etc.

If your reception is fixed in location, set and forget "wave-traps" may be for you. Put a parallel-resonant circuit in series with your antenna input, or a series-resonant circuit in shunt across the input to to reject or bypass the offending signal. If you have more than one offending signal, multiple traps may be used. You probably don`t have many problem signals at one location.

Best rergards, Richard Harrison, KB5WZI

Awesome,
I'm waiting for approval from the building management to put up the antenna on the roof. From my location, I'm hitting repeaters about 25 to 30 miles away, so I'm sure with the antenna on the roof, I'll go further, plus I could do packet better too.

Rickie

Only warning on baluns is that you need to use them around the
designed impedances otherwise they become very lossy. I had a
1:1balun that I noticed would heat up and cause the VSWR to move with
as little as 200Watts in. I took it down and put a 2.5K ohm load on
the output and measured 6 ohms on the input with the ant analyzer
(almost all resistive). Then I switch to 50 ohm load and I got 50 ohm
input. So the frequency I was trying to use my off center fed dipole
on didn't present enough of a load for the balun. Once I got down to
500 ohms or so, did I see the losses start to drop off.
FYI
Jerry

>

I can try, but have no expertise in this field at all! I believe the
following to be true...

Back in the good old days, the supply companies provided 3 conductors: Live,
Neutral and Earth.

For some reason (probably cost?) they did away with the need for a separate
Earth conductor by bonding Neutral and Earth together at the substation. The
buried cable used to bring the supply to homes has 'gaps' in the insulation
along its length, effectively connecting Neutral back to 'mother earth' at
these points. Since there are many of these along the length of the cable,
we get the term 'multiple earthing'. Only when the supply reaches your house
does Neutral get split from Earth again....

PME is a problem for radio amateurs because they may connect additional
metalwork in the ground to their Earth systems. (And because of PME they are
effectively connecting it to Neutral too....) If a fault in the buried cable
develops that breaks the outer Neutral/Earth connection, but leaves the live
intact then all the current supplied after the break will have to find
another way back to the substation through the ground... If your earth
system is connected to the (now disconnected) Neutral conductor then hey
presto a fairly low impedance path is available... Your supply (and all your
neighbours downstream of the fault!) can now complete its circuit through
YOUR earth system. That's a heck of a lot of current (= fires and
explosions!)...

Another risk: Your earth has some resistance.... Voltage=Current x
Resistance.... So there will be a rise in potential around your earth
system. In other words it won't be at 'Earth' anymore... Which means that it
is a problem if you are, and you touch it...

So that's PME! It's late and I rambled... I wonder if *anyone* understands
me?

As for ELCB that's a bit easier. "Earth Leakage Circuit Breaker" - a device
that sits on a supply line and monitors the current in the Live and Neutral
lines. In theory these should be equal because all appliances etc. will form
a circuit between Live and Neutral. If the currents are not equal then some
of the live current is flowing elsewhere (to earth probably, hence an 'earth

leakage') - the ELCB detects this difference and shuts off the supply. Most domestic ones trip at 30mA and reasonably quickly, the idea being that if it is a person that the current is leaking through, they might live. In large installations with lots of PC's and stuff the capacitors connected between the supply and earth in the power supplies can have a cumulative effect, leaking enough current to trip ELCB's - you can get special ones with a higher trip rating for these kinds of situations.

Oops, I rambled again...

HTH (a bit!)

Dan.

Hello everyone,

I have been looking around various websites for used antenna design/theory books but I am coming up with nothing of real interest. So, if anyone in the UK has some antenna books that they don't need or use please drop me an email.

These will be of great use to me not only at home, but for the club and other training projects.

TIA

Pete

5645. Re: FT-920 AND SB-220 ?!

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-30 02:03:27 UTC
From: Dan/W4NTI <w4nti@NOSPAMmindspring.com>
Message-ID: <auo9h0$7p7$1@slb3.atl.mindspring.net>
Source record: 128184

There is no need for a 'external antenna tuner' between the 920 and the 220.
The SB 220 has tuned input on 80/40/20/15 and ten.

If you keep the output of the 920 to less than 120 watts you wont really
need the ALC line to be hooked up.

The SB-220 has a high current antenna relay circuit. Read the
specifications on the rig and the amp to determine if they are compatable.

If they are not...Just build a external keying relay. Or hook a foot switch
to the AMP. Whatever works for you.

Tell me why I should care. I see no evidence whatsoever of RF the shack, like your lip burns or even less painfully. I can run my laptop (Compaq Armada 7400) on the internet doing downloads while running a KW (Johnson Thunderbolt) on my 40 meter loop. I did that this morning as a test since Rick Littlefield mentioned his problem with his computer.

I couldn't care less whether or not you could measure common mode current on my feedline. If there is any, it might be measurable but it is also insignificant and totally unrelated to the results I get using the antenna. I know you don't like hearing this, but the antenna works quite well in spite of your disbelief.

The various pros and cons being voiced on this subject remind me of something my grandfather said in the late 60s regarding "hippies" (remember them ?) He said......

"Long hair.....short hair.....what the hell's the difference once the head's blowed off."

At the time, I didn't realize how profound that statement really was - I thought it was just some comment on the (at the time current) Vietnam war.

Hope this helps!

PME = Protective Multiple Earth.

At one time the electricity supply companies used to run 3 cables to each house, L, N & E. About 50 years back (I'm not sure of the exact date) they reduced this to 2 , L & N.

To provide a local 'earth' facility they bond the N conductor to all the pipe work (water and gas etc) at the point where the supply enters the house, in the box that goes from the 1" dia "coaxial style" cable (which is not coax, just has a similar appearance) to the two 'tails' that go to the input of the meter.

There should be a notice on such installations.

ELCB = Earth Leakage Circuit Breaker

A device the detects an imbalance between the currents in the L & N and, if the imbalance exceeds a preset limit, turns off the supply. The limit is typically 30mA in a domestic environment. About 3x the benchmark lethal level.

Thanks for bringing that one up - I wondered when someone would.
Even with the shortest path from a shack to a ground point
outside, you would probably have at least 5m of wire.
At 30MHz, this would be half a wavelength and appear to be
an open-circuit at the shack if it was a perfect RF earth
at the other end. I believe that MFJ make a tunable RF earth
but I have no experience of using such a thing.

I'm in a similar situation. My shack is upstairs in the house.
Currently, my set-up is that I connect the chassis of equipment
to mains earth as an electrical safety but with cable that is
wound through a ferrite ring to reduce the possibility of
RF getting back into the mains. Secondly, all of my antennas
are balanced and fed via baluns. Also, each feeder has a number
of turns in the loft before it drops down so that it acts as
an RF current choke to try and keep RF out of the shack.
I haven't had any problems with RF in the shack or RF
getting into mains wiring.

I have heard of others that take this further and use an
RF earth to connect to the coax screen at the antenna
end, connecting to the balun close to that point, then use
ladder feed from the balun to the antenna. Obviously, this
means that you have a vertical ladder feed from ground level
upwards and this might be considered an eyesore by the XYL.
Plus you have the issues mentioned by others of disconecting
mains earth in PME situations as mentioned in detail by other

posters. For these reasons, and the fact I haven't had a problem with RF in the shack, I didn't do that.

If you are using unbalanced antennas such as a vertical or end-fed, then having a good RF earth close to the antenna is important. However, most sources suggest that a few copper rods is not an effective RF earth (unless you're right by the sea where ground conductivity is very high) and they suggest a lot of buried radials. Some people even bury chicken-wire mesh under the lawn so that they have a large surface area to form an effective ground plane.

Hope that helps,
David.

David Honey wrote:
"---you probably have at least 5m of wire. At 30MHz, this would be half a wavelength and appear to be an open-circuit at the shack if it was a perfect RF earth at the other end."

That would happen near 15 MHz were the earth return actually connected to that "perfect earth". The 5m wire would be 1/4-wavelength at 20m, and invert the impedance found at the far end. At the shack end, the earth impedance would be high but not infinite because of radiation resistance. Some of the r-f on a single wire radiates.

Near 30 MHz, the 5m earth return wire would be nearly 1/2-wavelength at 10m and try to repeat the impedance of that "perfect RF earth at the other end" in the shack. The problem of radiation and radiation resistance is larger for a 1/2-wavelength of wire than for 1/4-wavelength of wire, of course, given the same current in the wire.

Depending upon the rest of the antenna system, other than the earth return, radiation from the earth return may be advantageous or detrimental to the desired antenna function.

Best regards, Richard Harrison, KB5WZI

Source record: 128197

Al,

I looked at the JWMiller Chokes, and they are not that bad. Almost certainly OK for the HPF. I have some concern on the LPF, but since the design is so easy, and the inductors about a buck a piece, give it a try. Without going through the analysis, I think the effect of low Q inductors is to add to the passband loss of the LPF, and reduce the amount of rejection in the HPF. You can make up a rule of thumb approximation here, which is that the sum of the resistances of the LPF inductors should be small compared to 50 ohms. (If you had 5 inductors of 10 Ohms each, you would have 6db loss at DC, assuming a 50 Ohm receiver input).

If the program allows it, put the resistance values in also. For example, if you have a 220 uH inductor that has 11 ohms resistance, put both the L=220 and the R=11 into your model. You might also want to look at the Miller 52XX series for the LPF, they are bigger, but have much less resistance. The RF resistance is not the same as the DC, but at 500 KHz, it will be close .

There is not a whole lot of choice in ready made inductors. Most of the ones you see in catalogs are nanohenries, not microhenries. Others get very expensive. You might want to check out what Mouser and Digikey have

I will have to download " Elsie ", sounds like it would be useful.

5661. Re: Folded unipole for AM band

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-30 16:03:00 UTC
From: richardharrison@webtv.net
Message-ID: <16190-3E106E34-203@storefull-2314.public.lawson.webtv.net>
Source record: 128200

Jacques, ON5MJ wrote:
"-1485 KHz) particularly about transmission line connection?"

A folded unipole is 1/2 a folded dipole. The ground system of radials produces the missing half of the dipole by production of a virtual image of the 1/4-wave in the air.

Impedance at the drivepoint is half that for a dipole of similar construction. For a simple dipole, the radiation resistance at the feedpoint is near 74 ohms and the simple 1/4-wave vertical has a radiation resistance near 37 ohms.

For a simple folded dipole, the feedpoint resistance is near 300 ohms, and the simple folded unipole has a feedpoint resistance near 150 ohms.

At the feedpoint of the folded monopole, both ends of the skinny loop could be insulated from the earth and seoarate 75-ohm coax cables could be used to drive each end with their shields connected together and connected to the antenna ground system.

It is cheaper and easier to use a single coax to match the folded monopole through an L, T, or pi network.

The advantage if a matching network is required, may be with a simple 1/4-wave vertical. The transformation ratio between 50-ohm coax and a 37-ohm antenna is less than 75-ohm coax and a 150-ohm antenna. Yes, there are games to play with the sizes of conductors used in the unipole and adjustments which can be made in its feedpoint and overall length, but the above ground structure of the ordinary 1/4-wave vertical is simpler and cheaper.

Advantage of the folded unipole or shunt-fed tower is a directly grounded section. This helps lightning protection and gives a side for departure of lighting and other cables without needing chokes or other isolation devices. Also, skeletal coax lines may be a nearer match to the folded tower than to a simple tower and thus require less coil to make a match.

Folded and straight towers have near identical radiation characteristics. Going with the majority of users will likely be less trouble for you, if you are erecting a new tower to radiate on 1485 KHz. Set it on a base insulator. If you are taking advantage of a grounded-base tower which is already up, then shunt feed it or connect a wire to its top to make it a folded unipole. It will probably reguire the installation of a good radial (120) 1/4-wavelength, system as its other use was probably as a support for VHF or UHF antennas which required no grounding system.

Best regards, Richard Harrison, KB5WZI

No palms in CT?

At the beach, a vertical may work well because an excellent ground is available. A loaded short whip may even give good results when worked against the sea for an earth return. Jost a few blocks from the sea, the earth return may be poor however.

In the state park, you may need bamboo or fiberglass poles to erect your dipole as high as possible.

Ken,
I might have a solution. Leave the pole at
home. Take a ball of twine instead. Throw
ball of twine over tree limb, hoist antenna off
ground. If a 'droid' shows up, growl. Then
tell the droid that by interfereing with your
portable emergency operations station he/she is
crossing jurisdiction lines in to an area that
only the FCC has authority in. Cite PL-97-259
which deals with such interference and that
there is a federal preemption, and that he/she
needs to take his Smokey Bear bunns on down the
road. (If the 'droid' is female, I would suggest
changing 'bunns' to a less sexist portion of the
human anatomy.)...
If that doesn't work, try begging...
'Doc

Seems that 1/2WL would make a perfect ground wire. Seems that
an even multiple of 1/4WL is what you are talking about.
5m of wire on 20m would be a worst case ground.

All I asked you to do is to prove your assertion that there is
"no RF in the shack". I didn't say you were lying. If what you
said is true, you could win the $1000 bet I made with you. Was
what you said true?

5668. MAXX automatic antenna tuners

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-30 17:41:32 UTC
From: G Blair <gblair@sympatico.ca>
Message-ID: <pan.2002.12.30.17.41.31.747751@sympatico.ca>
Source record: 128207

Anyone used the MAXX antomatic antenna tuners, http://www.maxx-com.com/?

How well do they work?

If you have no first hand experience or otherwise know nothing about this tuner, please do not respond to this post.

5669. Re: What kind of balun do you use for HF antennas?

I will take that bet CAM, I have no balun and no RF in the shack.

But then again my shack is in a screen room and I have no transmitter.
Please forward the $1000 to my payameigo account.

With all good wishes
Fred W4JLE

During the recent ARRL 160M contest the SWR on my several-year-old GAP antenna suddenly went screwy. Turned out I'd scorched the capacitive compensating module at the top of the antenna. GAP sent a replacement FREE (including shipping) in time for me to compete in the Stew Perry Topband Challenge.

Thanks, GAP.

If you want to get RF out of the shack, use a quarter-wave
counterpoise, adjusted in length for maximum effect.

Half a wavelength will merely keep the volts where they are, just
where you *don't* want them.....

hello guys,

what would be a typical FM-radio-station-antenna-height? I assume it will be dependent on budget and terrain. Can anyone also say the same parameter for a AM (SW) radio station, also if possible for UHF-tv-station.? To be more general, I would appreciate info about any type of comm-service antenna-height.

best regards,

zender

Zender Swonssen wrote:
"What would be a typical FM-radio-station-antenna height?"

About 300 meters or 1000 feet. The distance in miles to the radio horizon from 1000 feet is:

sqrt of 2000 or 45 miles.

The formula is: D = sqrt 2H

The formula is based on normal propagation over a smooth earth. This is "line-of-sight" propagation for VHF, UHF, and higher frequencies. It works for lower frequencies but these have other options besides "line of sight" propagation.

HF waves are subject to reflection from the ionosphere to great distances beyond "line-of-sight". Medium and lower frequencies are also subject to following the earth`s curvature for propagation over long distances. The sending and receiving antennas don`t need to be able to "see" each other.

For "line-of-sight communications, if the sender and receiver can "see" the same grazing point, they can "see" each other and may be able to communicate. To extend the range, the heights of either the sending or receiving antenna may be increased.

Best regards, Richard Harroison, KB5WZI

Recall that a 1/2-wavelength repeats impedances from end-to-end.

Put one end to a good ground, and that good ground is repeated at the opposite end except for radiation from the wire.

I think Cecil was proposing ground-plane wires, 1/4-wave long and open-circuit on their far ends, which invert the open-circuits back at the shack end and thus produce a low-impedance current path at the shack for the operating frequency, just as they are used with a ground-plane antenna.

Best regards, Richard Harrison, KB5WZi

GUYS !!! You have reached the nit-picking stage! Is it time to wrap this discussion up?

You can put a balun or an unun or a current balun [RF Choke] on the antenna and feed lines all you want and you will ALWAYS have RF in the shack! ALWAYS! On 160, 80 and 40 meters you are sitting in the near field of the antenna and that couples RF currents into everything. On 30 through 10 meters you are sitting in the transition zone of the RF fields and have RF in the shack. On 20 meters and running 1 KW the power lines in my house show significant RF currents and the antenna is 70 feet away and 50 feet high! Maybe on 6 through whatever IF the antennas are far away and high you will be in the far field.

That's why the FCC has imposed RF Exposure limits on us!!

If it solves a problem use it!! If there's no problem why make one?

Let's change the subject.

Is this the same maxx-com that uses a loading resistor? If so, why
spend a thousand dollars on a transceiver to heat up a resistor? You
can heat up the resistor with 110vac right out of your wall plug.

1/4WL is good if the other end is open-circuited. 1/2WL is good
if the other end is grounded. If the other end is grounded, the
volts will be close to zero with 1/2WL.

MY guess this is the same company exposed in QST years back- an elevated resistor sealed in epoxy- quite a profit margin.

It's a reasonably good transmitting antenna given its footprint, but noisy
on receive (the curse of verticals!). To receive I use a horizontal loop
and during contests string some temporary beverages.

Don't know if that height above is the true average height of all US FM stations. Those antenna heights can vary from less than 50 to over 600 meters above average terrain (not height above local ground elevation). The FCC assigns FM stations to different heights and radiated powers according to their class of service. The maximum power radiated toward the radio horizon can vary from a few hundred watts to over 100,000 watts

>Am I asking for trouble with 500 w?

I find that TV sets (on cable) within 20 ft of my dipole are affected by 100 watts. At 30 ft., nothing. I think it is caused by RF induced in the 110V house wiring.

Based on this limited sample, I would think you are OK if your neighbors' houses are 50 ft from your antenna. The answer is probably different for RF devices, like cordless phones, antenna TV's, etc.

I will let you know for sure in a week or so: My 600 watt amp is due back from Yaesu and my nearest neighbors are around 40 ft from my dipole.

QST or 73 X-rayed one of their "antenna matchers" years ago. It was nothing but a block of resin with random junk inside... nothing connected to the coax. I wouldn't risk it. It could be real. However, they also could have been waiting for everyone to forget the last scam.

Not if you comply with your licensing conditions.

It's only another 7dB but the receiving-end will notice a significant increase in your signal strength - about 1 S-unit.

Increase power from 100 to 500W and all voltages and currents increase by Sqrt(5) = 2.2 times.

Watch for things like arcing-over in tuners, overheating of loading coils, traps, baluns, TLI (SWR meters), and more painful burns from RF in the shack. You may suffer from more RF feedback into the mike, or feedback around the 500-watt PA which at present does not exist.

The guiding principle is to ensure ALL components in the radiating system have adequate power ratings, paying particular attention to inter-equipment bonding and grounding.

If you have a good friend who will trust you wih his higher power rig for a few days, even a few hours, then you are laughing. Just replace everything which issues smoke or sparks. ;o)

No need to do anything about interference until somebody get any. Then the equipment which is being interfered with should be attended to first. After all, if YOU are complying with the Law it must be the other fellow's equipment which is defective. In such situations, of course, a gentlemanly, charitable attitude works wonders. What a pity some Governments don't follow such peaceful guidlines.

Sorry about the bet CAM. We live in an RF saturated world. I even have a special RF signal in the shack so I can watch the Boston Bruins tonight!

The only way you'll know is to borrow an amp and try it.
I run 500 W with no problems. N5AQM can't run more than
100 W in Chandler, AZ without his neighbors objecting.

5696. Automatic Antenna tuners....

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-31 00:45:51 UTC
From: Henrik <henrik>
Message-ID: <3e10e8c0$0$198$edfadb0f@dread16.news.tele.dk>
Source record: 128135

Hi, thanks for reading, and happy new year!

Just fell over this homepage for a coupler:

http://www.maxx-com.com/index.html

and as I recognise it, is a "passive" tuner....where the rf selects the route to the antenna through passive components, hence no supply of power, relay's or other active components to fry or wear down.....

Has there been any diagrams published for home brew...and is it a true and good alternative to active tuners?

H.

5697. GAP VERTICAL ANTENNA PERFORMANCE

Anyone had any experiences with either the Titan DX or the Challenger DX vertical antennas produced by GAP Antennas? If you had it to do all over again, would you purchase either of the antennas again?

Just looking before I leap.

Thanks.

Nope! But you will have to assure that your station complies with all aspects of 47 CFR 97.

I run 1 KW on 80 through 10 meters. All neighbors have their tv's on cable. So far so good. One neighbor bought a radio shack splitter and 2 50 foot pieces of RG-6 for 2 additional tv sets. So far so good? Not so!! He bought the cheapest cable made/sold by Radio Shack. Now, I could have insisted the problem is his and he should use higher quality cable. I would be right! And, I'd have a P.O.'d neighbor.

Instead I showed him the cable system in my house, 3 tv's on high quality Belden RG-6. Then I demonstrated that I had no tv problems!

We wound up sharing the cost of 100 feet of RG-6 from ATT Broadband. [my share $30.00]. $30 is a cheap investment when I have spent over $7000 on a ham station.

Next potential issue: telephone interference!! Get some K-Comms and just give them away!!

Next potential issue: VCRs: good luck! I gave up on a Panasonic TV/VCR combination. The VCR mixer is always powered! It is not a requirement to be free of interference on VCRs [no selectivity]. [I did adjust my operating hours around this neighbors Saturday Night Movie.]

Next potential issue: Stereos. Clamp on ferrite for speaker leads solves most issues.

Next potential issue: Computer powered speakers. good luck! see above. Not a requirement to be free of interference on computer powered speakers. I keep a COMPAQ notebook right next to my amplifier and demonstrate no problem and have them contact their local computer fixit guru.

Bottom line. Be on good terms with your neighbors. Let them know when and how often you operate. If they even 'think' there is an issue make sure they let you know before their blood pressure goes up. Be proactive in solving the interference issue. [caution: don't open any neighbor's equipment! Provide the filters free and show them how they are installed at YOUR location and recommend they contact the service technician]

I keep about $200 worth of K-coms, HP filters, clamp on ferrites, ac line chokes, etc. as part of my station.

Having a neighbor actually see that your house is interference free is a strong indicator that their house can also be interference free, but with some additional effort. I operated at the KW level for over 20

years. My neighbors knew it and were not bothered.

Funny how this new dangerous 'exposure' becomes the answer to such a simple 1930s question. All thats fine and good since it has now become a "consumer's measuring stick".
But, going from 100 to 500 watts is what, 6-8 db increase?
In practice the scale runs something like....
1. There's a guy with a big antenna up the street and I think Jerry Springer sux so the big antenna must be the problem why I can't receive better programming.
2. There's a guy with a big antenna up the street that interferes with Jerry Springer.
3. There's a guy up the street who thinks he is better than Jerry Springer.
4. There's a guy up the street who is infringing on my rights to watch Jerry Springer.
5. When that guy up the street put up them antennas my water heater died and Jerry Springer can't help me.

About ninety percent of TVI cases involve such mentality. Your 6 or 8 db increase won't be the determining factor.

Richard Fry wrote:
"Don`t know if that height (1000 feet) above is the true average height of all US FM stations."

I don`t either.

My dictionary says:
"Typical" means pertaining to, or of the nature of---." It says nothing about averages or median values. The question was:
"What would be a typical FM-radio-station-antenna height?"

I went to work for a broadcaster who had a highly profitable AM operation on 790 KHz in 1949. He also had an FM affiliate on a tower on Ennis Street in downtown Houston. It is still there, but the call sign and programming are different. It now speaks Spanish. FM time couldn`t be sold in 1949. It was given as a "bonus" to advertisers on the AM affiliate.

The call leters of our FM affiliate were indicative of its programming. The call sign was: KOPY. Its main value to us was as a backup to the program line serving the AM transmitter site out of town.

I think our FM operation was typical at the time. 1000-foot towers were used by serious entrepreneurs who hoped to profit from FM in the long run. The broadcaster wanted the range of his FM affiliate to rival his AM affiliate if he were ever to make a go of it. Most were convinced that FM would eventually pay off due to the superiority of FM reception. You had to have pioneering FM broadcasters if there were ever to be a critical mass of listeners to make FM broadcasting economically viable. Today, a broadcaster has to at least meet the competition to reach listeners in a large metropolitan area.

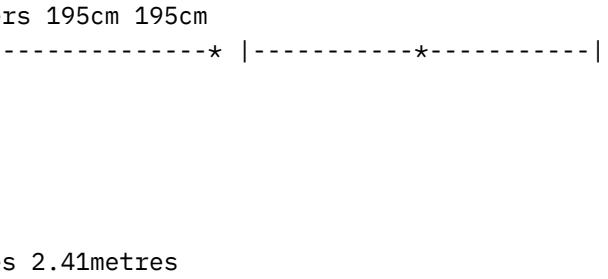
Unfortunatelly, I can't drop wires down to neighbour's balcony, he is a
nut.

There are only two possible setups in my limited space balcony would a
"V" dipole turned 90 degrees, something like this:

1.] 2.]



Will any of those schemes work as dipole ? I'll build an impendance
transformer (ratio 9:1, by FT82-77 Amidon toroid core, which is suitable
for frequency range 100kHz up to 30 MHz.)

Maybe a better approach would be a "random wire" antenna instead of a
dipole, as one peace of wire, horizontal + downloead = 6.26 metres ?
Will the transformer described above somehow help cover signals
100kHz-30 MHz ? (receiving SW only).

Someone in this newsgroups suggested a mobile CB whip placed horizontaly
with an impendance transformer ratio 9:1, I'll try that too, but first
I'd' like to build some antenna with the cheapest material: a wire, if
possible.

Thanks.

Carefully read the instructions. Apparently you either have not initialized
it or have it overloaded. That design is very marginal as far as
synchronization is concerned anyway.

RFI problems or not. It's a fairly safe bet
that if you aren't having problems now, you
probably won't with 500 watts. Even if you do
have RFI problems it shouldn't be too hard to
do what needs to be done to clean up any problems
with your equipment. After that, it isn't
~your~ problem anymore...

Zender Swonssen wrote:
"Can anyone also say the same parameter for an AM (SW) radio station?"

There are several answers. Medium wave stations use vertical antennas because there is no groundwave propagation of horizontally polarizeed waves.

Almost any vertically polarized antenna will do for producing vertically polarized waves but broadcasters have to meet minimum efficiency requirements and a 1/4-wave meets the minimum. An increase up to 5/8-wavelength produces more field strength without much added complexity, but most broadcasters are satisfied with a 1/4-wavelength radiator.

When vertical antennas are used for short wave, 1/4 wave is the usual antenna length as in medium wave broadcasting.

Very few shortwave broadcasters or other commercial users of ionospheric propagation use vertical polarization. Most use horizontal antennas and these are usually 1/2-wave antenna elements or dipoles unless rhombics or Beverage antennas are being used. These are usually several wavelrngths long. Many stations use curtain antennas of dipoles and reflectors. In the Andes, full-wave quad elements are used to avoid corona discharge at open-circuit ends of elements at high altitude.

Warning, I am reciting this from memory without reference to any book, so it may be subject to error. I have worked in medium wave stations, shortwave stations, and erected several stations in the Andes, but that was long ago, and I may have memory lapses.

Best regards, Richard Harrison, KB5WZI

I have used a Challenger for six months. It has done much better than I expected. Good for scheds from NY -> NC on 40m. For casual DX, I have worked >160 countries since I set it up. I also use it on 2m with my base station.

I sometimes use a small amp, sometimes barefoot. Generally, if I hear the station I can work it.

This was a good investment of time and money.

Best offer over the next week or it will be left out for the trash man to take. This is the end of a coil of cable TV hardline. Not sure the exact length - somewhere between 250 and 300 feet using the old Pi times D times the number of coils method. I live in Central Mass and unless you want to pay for shipping, meet me nearby to pick it up.

"No groundwave propagation?" Not really. Medium wave broadcast stations use vertical polarization because propagation losses for horizontal polarization are higher. But those losses are not infinite, by any stretch.

I'm looking for plans for a 2M antenna for mobile/portable use - school and scout camp demos, hotel rooms, and so on. I'm looking for a design that will "fold" or "roll up" then be taken out and hung in a window or from a tree in use. If *absolutely* necessary I would use something rigid with dimensions that would fit the bottom of a car trunk. I can trade portability for lower performance. Most sites will be near a repeater and some 2M activity. I'll be driving it with an HTX-252 (10-25 watt radio). First attempt at antenna consutruction. Recommendations or URLs to plans? TIA ...

I've had my Titan DX since August 2001. My rig is an FT817 qrp rig
so my max power is only 5 watts. Still, if I can hear a station I generally
can work them.

I also use it on 6 meters (great SWR) where it is only an S-unit or two
down from my Comet 4 element 6 meter Yagi.

On 2 meters it often outperforms my Hy-Gain 14 element yagi but
the yagi, like my 6 meter antenna, is horizontally polarised.

Despite GAP's instructions I loosley guyed the antenna three ways
with parachute cord - I just didn't want the antenna swaying in the
wind and getting metal fatigue

I have found that the Titan DX is everything the manufacturor says
it is and more. Well worth the price. There are more reviews at:

http://www.eham.net/reviews/detail/315

Richard Fry wrote:
"But those losses (to horizontally polarized waves traveling the earth`s surface) are not infinite by any stretch."

I had written: "---there is no groundwave propagation of horizontally polarized waves."

In my ancient memory are numerous affirmations of high ground attenuation of horizontally polarized waves. No attenuation is infinite. But some are are infinite for practical purposes, and by only a slight stretch.

I recall that somewhere in Terman`s 4th edition are three solid statements of this single fact that there is no groundwave propagation of horizontally polarized waves. I never expected to be contradicted on this universal observation.
So, I didn`t book mark the pages.

A reflection is out-of-phase with the incident wave. If they are stacked one on top of the other like batteries in series, they add. If they stack side-by-side each other like two cells connected plus to minus and minus to plus, they short out.
The additive battery is like vertical polarization. The shorted cells make the horizontally polarized case.

From page 803, paragraph 22-2 of Terman`s 1955 edition of "Electronic and Radio Engineering":
"The ground wave is vertically polarized, because any horizontal component of the electric field in contact with the earth is short-circuited by the earth."

That`s good enough for me. I have no desire to dig out Terman`s other two similar statements. They are in there but the story is the same in all chapters where it appears. Other authors say the same thing. Reg Edwards says they all copied from each other anyway. I do recall Terman having diagrams including antennas with their reflections in the earth illustrating the same phenomenon. But I don`t want to go looking for them now.

Terman has been around for 70 years or so. The errors are few.

Best regards, Richard Harrison, KB5WZI

Source record: 128165

tennant,
Lots of option! One I like uses three coat-hangers,
an SO-239 'chassis' connector and some string to hang
it with. Straighten the 'hooks' on two of the coat-
hangers and scrape all the enamel (or whatever it is)
off. Thread the straightened hook through opposing
holes in the base of the SO-239. Twist the 'hook' back
onto it's self to hold the coat-hanger parallel to the
base of the SO-239 (the 'loop' of the hanger horizontal).
In the center pin connection of the SO-239, solder the
third coat-hanger's 'hook' after straightening and
scrapeing it. To adjust the length of the third hanger
for resonance, grab the center of the bottom part of the
hanger and pull it up. When the 'length' of the vertical
element coat-hanger is right, quit stretching it.
It looks 'Rube Goldberg'ish' but that's what makes it
so great! Works pretty good at schools and ham club
demo's, they just ~know~ your a true ham... cheap!

Gentlemen, gentlemen, with all your horror stories you will frighten Martin
in to giving up amateur radio.
We need to answer his questions, and to do that we need to define the
problems, as I see it they are
1 Is his supply PME, and if so what is to be done about it, and what is to
be done to separate the RF noise from the mains, and the mains earth.
2 The RF earth lead could be a resonant length on some bands giving high or
low impedances and voltages, what can be done about it, or even does he need
an RF earth connection at all. What can he do to ensure that no high voltage
RF conductors can come into contact with anyone.
3 What can he do about lightening protection.
4 What can he do to ensure he does not create TVI or BCI to his neighbours.
All of the forgoing questions can be answered, but Martin deeds to supply a
few more details about
his home and surroundings.
some of the questions are as follows:
Is he in the UK if not where is he.
What kind of electricity supply does he have, overhead or underground
feeder, is it PME,
Is his building a high rise block, if not what type/height is it.
Where are the antenna's going to be mounted, on his building or on separate
self supporting structures or other buildings.
Are the antenna's and feeders going to be coax, balanced, or end, fed. Are
they resonant, broadband, or tunable.
Can he use an RF earth or counterpoise.
Martin wants the safest, cost affective solutions for his installation. All
of the problems and hazards are curable with a little care, and he will
still have a suitable and sensitive installation.
I recommend he obtains a copy of the RSGB book "HF antenna collection" which
has the Peter Chadwick article "the Killing ground" reproduced in it.
Another version is in the RSGB Book "The radio amateur guide to EMC.
This reply is already too long so I will put more answers regarding ELCB's
and RCCD's and PME in another email.
regards
Ray

Ken-

The company that makes the Hamstick antennas, also sells a bracket that allows two mobile whips to be mounted as a dipole. They don't have to be Hamsticks, but those are cheaper than other alternatives.

I have one mounted on a five foot section of aluminum TV mast, supported by a roof-mount bracket from Radio Shack. The bracket acts like a tripod when sitting on the ground.

What about bringing along your own "trees" in the form of TV masts and roof-mount brackets? Perhaps some kind of tent-peg approach would keep the brackets from tipping over from the wieght of the antenna wire.

Tenant-

Here is a design posted in years past by someone else, that is well worth re-posting. For the ASCII drawing to line up correctly, you need to use a mono-spaced font such as Courier.

I tried one and it worked very well. You can use a small-tipped soldering iron to melt a hole in the insulation at the top, to use a string to tie it to a tree.

2M Jpole with 300 ohm twin lead
>From: kinsman@ektools.UUCP (Andrew A. Kinsman)
Newsgroups: rec.ham-radio
Organization: Eastman Kodak, Dept. 47, Rochester NY

The following is a description of a J-Pole antenna made from 300 ohm TV twin-lead. Quite a few of the hams in the area have successfully built one or more of these antennas. They have quite a few advantages which include improved performance for 2-meter HTs, portability, and last, but never least, they are inexpensive.

```
| | do not short this end.
| |
| |
| |
| |
| |
54" | |
| |
| |
| |
| 1/4" gap
| |
| |
| | 16 3/4"
coax ctr conductor=>* *<= coax shield
| |
1 1/4" | |
```

-*-
solder the twin leads together at bottom

1. Start with 54 1/2" of TV twin lead (foam core does not work as well)
2. Strip 1/2" of insulation at bottom and solder wires together.
3. Measure 1 1/4" from soldered wires and strip insulation on both sides. This is the solder point for a coax feedline.
4. Measure 16 3/4" from bottom and cut out 1/4" notch on one side.
5. Feed with a length of RG58U coax. Tape coax at feedpoint to the twin lead for strength and weather protection.

I have also attached an alligator clip to the plastic on the top of the antenna in order to conveniently hang it. I am successfully using one in my attic to avoid any CCNR problems. I have another that I can take with me camping, sailing, etc.

This design has appeared on many BBSs and in club newsletters; the earliest reference that I know of is a Jan. 1984 D.A.R.C. antenna article by James Burks, KA5QYV.

Enjoy,
N6UBM

5733. 160 Meter K9AY Small Loop Issues

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-31 18:33:14 UTC
From: wa5bdu@yahoo.com
Message-ID: <ca1a467b.0212311033.769d6281@posting.google.com>
Source record: 128072

I built the K9AY compact 160 meter receiving loop from the September, 1997 QST and don't seem to be getting the directivity I expected. I wonder if the newsgroup's members have any pointers. Some things I'm considering--

Do I need a good common mode choke on the coax to the receiver?
Is it critical that the loops are at exactly 90 degrees to each other?

There's always the possiblity that I've wired something wrong and I will be going over that again when I get some daylight at home. I did check the 9:1 transformer with an antenna analyzer and it seems to work fine.

"Propagation losses" !!!
Is this 'losses' due to penetration through the ionisphere?
Since a previous post pointed to the FCC requirement of minimum
'efficiency'
which I assume is ground losses (vertical use) this 'propagation
losses' throws me into a loop (no pun intended)when considering
verticals versus horizontal antennas. Could you please expand on the
cause and implications of these losses
with respect to medium wave broadcasting ?

I'd like to hear some user comments on this active loopstick antenna as I've
been thinking of buying one vs. making a loop. My main interest would be
VLF and 160 meters unless of course it's a great performer on HF. I'm
guessing the parts cost is about $100.00!
tnx

Hi Art,

The losses relate to Richard Harrison's quote:
>>From page 803, paragraph 22-2 of Terman`s 1955 edition of "Electronic
>>and Radio Engineering":
>>"The ground wave is vertically polarized, because any horizontal
>>component of the electric field in contact with the earth is
>>short-circuited by the earth."
which is significantly true in practical life, but clearly, ground is
not the best of short-circuits to be found. This is a hedge bet to
offer that since ground is not a perfect short, it must then be a
lossy short and that someone will observe a weak horizontal signal at
some distance beyond what a perfectly conducting earth would have
allowed.

Either way, the loss is due to ground absorption for a mode eminently
suited to pump power straight into it. One of the simple tests of

this is found in the old wive's tale that horizontals do not benefit by ground work.

Place a ground screen under a horizontal and the ground loss goes away. As a consequence, that now rescued power must be expressed in other directions (straight up is one principal beneficiary); and for a random population of antennas, that would translate into some gain, somewhere useful. How much gain is another matter and hardly suited to the acid test of "does it make 1dB difference?"

Broadly defined it is the attenuation of a radio wave between the transmitting antenna and the receiver location. Some of the factors involved are: path length, frequency, polarization, earth conductivity/dielectric constant, obstructions, and atmospheric conditions.

I presume you mean K0BRA's article. It's not a loopstick antenna.
It's an active antenna. Your estimate of parts cost is about right.
The critical parts are really the power transformer (you need low
capacitance between windings to prevent coupling in to AC power
system) and of course the active device.

Performance on LF is pretty good, IF you get it in the clear. That's
most of the problem. As for the rest of the SW band, if you can
afford to put up a random wire, it will probably work just as well.

In my opinion, what this antenna does for you more than anything else
is get you some isolation from most of the noise sources in your
house. If you are plagued by TV flyback hash, fluorescent lights, the
VCR and most other digital nasties, then this is the antenna for you
--provided you can get it away from or above your house.

I found it necessary to limit coverage to below 10 MHz as per the
article. In addition to that, the IMD from sources such as LORAN can
be fierce. If your receiver is up to the task, have at it. But don't
expect an inexpensive SW receiver that just happens to cover LW to do
something good with it. Be prepared to add additional bandpass
filtering or perhaps an attenuator between this active antenna and
your receiver.

If you can't find the CP666, check AMRAD's web site for details on
using a more common JFET, such as the U310. IMD Performance will be
reduced substantially, but if you live in a rural area you may not
care.

If you have other construction questions, feel free to e-mail me,
though I'm hardly the expert on this. If you look on the AMRAD web
site you'll find K0BRA right there...

They have yet to "DO" me and they haven't done Mr Chadwick! Nor his wife when as I remember him telling me she told them where to go when they did try to provide PME at his home.

The Earth at your premises is YOUR responsibility not the Local supply companies! And they will either refuse to connect on a new installation - or disconnect on an old installation if it doesn't meet the required standard.

From someone with the PME disconnected for ever!

AND Someone who knows!!

I thought I mentioned -- but didn't -- that I have a new 20 ft. Black Widow crappie pole ($17 from Cabela's) that I intend to use as the feedpoint support where there are no trees. Actually, I can get it 23 ft up because I keep it in a 4 ft PVC pipe case that doubles as the bottom section, adding another 3 ft.

If that doesn't work, I'll spring for the MFJ item -- which goes to 30 ft. That is a much, much better height (i.e. 3 dB better) for 80M. But $80 for the MFJ pole is not cheap -- and you can't fish for crappie with it, either.

Art Unwin wrote:
"Propagation losses"!!!
"Is this losses due to penetration through the ionosphere?"

Good question. The answer is in a large part, yes.

Energy is neither created nor destroyed. Suppose the earth were conductive like sea water. Not much heat generated upon wave reflection from its surface. But, tangential to the earth`s surface, we have direct radiation from a horizontally polarized antenna and an almost equally strong reflected signal. The reflected signal is out-of-phase with the direct signal from our viewpoint. Distance traveled to us is nearly the same, so the signals remain equal in strength and out-of-phase arriving at our surface of the earth location. Strength of this combination is very nearly zero where we stand.

Art Unwin has, I believe, a copy of Terman`s 1955 edition. On page 886 is Fig. 23-23 which illustrates what happens with (a) horizontal polarization, and (b) vertical polarization. In (a) there is no signal along the horizontal. In (b) the strongest signal is along the horizontal.

As Art suggested, the signal from the horizontally polarized antenna being strongly reflected goes elsewhere and this is indeed penetrating the ionosphere during daylight hours. At night this higher angle radiation is reflected to earth for medium frequencies in most cases. The concern of the broadcaster is that this will reduce the radius covered by his station through distructive interference with his ground wave (fading).

The broadcaster wants maximum ground wave and, in nearly all cases, minimum sky coverage especially at high angles of radiation where the signal may be returned to earth close to the transmitter.

Best regards, Richard Harrison, KB5WZI

I would say it is always a good idea to put
a common mode choke on a beverage or
K9AY type antenna. You really don't want
any chance of common mode current back
feeding into your antenna. With a low
output antenna like a K9AY, I would think
it is even more critical. After all, your
feedline shield is an antenna.

I use a common mode balunk on a short
(400') beverage, and the antenna works great.

Asa,
I have had one for some time. It tunes up on all bands great but then so does my heath kit dummy load. Overall it works but I get much better results with my 130 ft dipole fed with 450 ohm ladder line and my total investment was less than $30 for it. Bottom line is some folks swear by then and others swear at them.

Richard Fry wrote:
"Broadly defined it (loss) is the attenuation of a radio wave between the transmitting antenna and the receiving antenna."

That might be called "path loss".

The FCC publishes and includes in its rules "Ground Wave Propagation Curves". There are separate sheets for each few percent of frequency (3% to 5% or so) for the medium wave broadcast band. The same dielectric constant is assumed for all curves. Conductivities range from 0.5 MMHOS / M, to 5000 MMHOS / M (no Siemens yet on my charts). Charts are based on 100 MV / M at one mile from the antenna, and give millivolts per meter at any distance from the antenna on a curve corresponding to a certain soil conductivity. So, for the FCC, medium wave path loss is a function of of resistivity in the soil.

Best regards, Richard Harrison, KB5WZI

I gotta agree with Asa ... I had a Titan for 6 months, and was glad to
find a buyer for it (I lost a bundle on it, though). My wires do a
MUCH better job on all bands, and the highest one is only 30 feet. I
previously had a Cushcraft R5 (not a great reputation), and thought
that it did better than the GAP, too.
